## CONTENTS

1 dnsdist Overview ........................................... 1
   1.1 Running dnsdist ........................................ 1
   1.2 Questions, requests or comments? .................. 1

2 Installing dnsdist .......................................... 3
   2.1 Installing from Packages ............................... 3
      2.1.1 Debian ............................................ 3
      2.1.2 Red Hat ........................................... 3
      2.1.3 FreeBSD .......................................... 3
   2.2 Installing from Source ................................. 3
      2.2.1 From tarball ....................................... 4
      2.2.2 From git ............................................ 4
      2.2.3 OS Specific Instructions ......................... 5
      2.2.4 Build options .................................... 5

3 Quickstart Guide ........................................... 7
   3.1 Running in the Foreground .............................. 7
   3.2 dnsdist Console and Configuration .................. 7
      3.2.1 Changing Server Settings ....................... 8
   3.3 Restricting Access .................................... 9
   3.4 Securing the path to the backend .................. 9
   3.5 More Information ..................................... 9

4 Running and Configuring dnsdist ......................... 11
   4.1 Running as unprivileged user ......................... 11
   4.2 Understanding how queries are forwarded to backends . 11

5 Packet Policies ............................................. 13
   5.1 Packet Actions ......................................... 13
      5.1.1 Examples ......................................... 13
   5.2 Rule Generators ....................................... 14
   5.3 Managing Rules ....................................... 15
   5.4 Matching Packets (Selectors) ......................... 21
      5.4.1 Combining Rules .................................. 27
      5.4.2 Convenience Functions ........................... 28
   5.5 Actions ................................................ 28
   5.6 Objects ............................................... 45

6 Statistics .................................................. 47
   6.1 acl-drops .............................................. 47
   6.2 cache-hits ............................................ 47
   6.3 cache-misses .......................................... 47
   6.4 cpu-iowait ............................................ 48
   6.5 cpu-stein ............................................. 48
   6.6 cpu-sys-msec ......................................... 48

Caching Responses

Exporting statistics via Carbon
  8.1 Setting up a carbon export
  8.2 Query counters

Working with the dnsdist Console

DNS-over-HTTP/3 (DoH3)
  10.1 Incoming
    10.1.1 Advertising DNS over HTTP/3 support

DNS-over-HTTPS (DoH)
  11.1 Incoming
    11.1.1 Advertising DNS over HTTP/3 support
    11.1.2 Custom responses
    11.1.3 DNS over HTTP
    11.1.4 HTTP/1 support
    11.1.5 Internal design
    11.1.6 Investigating issues
  11.2 Outgoing
    11.2.1 Internal design

DNS-over-QUIC (DoQ)
  12.1 Incoming

DNS-over-TLS
  13.1 Incoming
  13.2 Outgoing
  13.3 Investigating issues

DNSCrypt

Configuring Downstream Servers
  15.1 Healthcheck
    15.1.1 Lazy health-checking
  15.2 Source address selection
  15.3 Securing the channel
  15.4 Securing the path to the backend

Dynamic Rule Generation
  16.1 DynBlockRulesGroup

</table>
dnsdist is a highly DNS-, DoS- and abuse-aware loadbalancer. Its goal in life is to route traffic to the best server, delivering top performance to legitimate users while shunting or blocking abusive traffic.

dnsdist is dynamic, its configuration language is Lua and it can be changed at runtime, and its statistics can be queried from a console-like interface or an HTTP API.

A configuration to balance DNS queries to several backend servers:

```bash
newServer({address="2620:fe::fe", qps=1})
newServer({address="2620:fe::9", qps=1})
newServer({address="9.9.9.9", qps=1})
newServer({address="2001:db8::1", qps=10})
newServer({address="[2001:db8::2]:5300", name="dns1", qps=10})
newServer("192.0.2.1")
setServerPolicy(firstAvailable) -- first server within its QPS limit
```

1.1 Running dnsdist

If you have not worked with dnsdist before, here are some resources to get you going:

- Install dnsdist.
- To get a feeling for how it works, see the Quickstart Guide.
- Running and Configuring dnsdist
- The Packet Policies page covers how to apply policies to traffic
- There are several Guides about the different features and options
- Advanced Topics describes some of the more advanced features
- Reference Guides has all the configuration and object information

1.2 Questions, requests or comments?

There are several ways to reach us:

- The dnsdist mailing-list
- #powerdns on irc.oftc.net

The Open-Xchange/PowerDNS company can provide help or support you in private as well. Please contact Open-Xchange.

This documentation is also available as a PDF document.
dnsdist only runs on UNIX-like systems and there are several ways to install dnsdist. The fastest way is using packages, either from your own operating system vendor or supplied by the PowerDNS project. Building from source is also supported.

### 2.1 Installing from Packages

If dnsdist is available in your operating system’s software repositories, install it from there. However, the version of dnsdist in the repositories might be an older version that might not have a feature that was added in a later version. Or you might want to be brave and try a development snapshot from the master branch. PowerDNS provides software repositories for the most popular distributions. Visit https://repo.powerdns.com for more information and installation instructions.

#### 2.1.1 Debian

For Debian and its derivatives (like Ubuntu) installing the **dnsdist** package should do it:

```
apt-get install -y dnsdist
```

#### 2.1.2 Red Hat

For Red Hat, CentOS and its derivatives, dnsdist is available in EPEL:

```
yum install -y epel-release
yum install -y dnsdist
```

#### 2.1.3 FreeBSD

dnsdist is also available in FreeBSD ports.

### 2.2 Installing from Source

In order to compile dnsdist, a modern compiler with C++ 2017 support and GNU make are required. dnsdist depends on the following libraries:

- Boost
- Lua 5.1+ or LuaJit
- Editline (libedit)
- libfstrm (optional, dnstap support)
• GnuTLS (optional, DoT and outgoing DoH support)
• libh2o (optional, incoming DoH support, deprecated in 1.9.0 in favor of nghttp2)
• libcap (optional, capabilities support)
• libsodium (optional, DNSCrypt and console encryption support)
• LMDB (optional, LMDB support)
• net-snmp (optional, SNMP support)
• nghttp2 (optional, outgoing DoH support)
• OpenSSL (optional, DoT and DoH support)
• protobuf (optional, not needed as of 1.6.0)
• quiche (optional, incoming DoQ support)
• re2 (optional)
• TinyCDB (optional, CDB support)

Should `dnsdist` be run on a system with systemd, it is highly recommended to have the systemd header files (`libsystemd-dev` on Debian and `systemd-devel` on CentOS) installed to have `dnsdist` support `systemd-notify`.

2.2.1 From tarball

Release tarballs are available from the downloads site, snapshot and pre-release tarballs can be found as well. The release tarballs have detached PGP signatures, signed by one of these PGP keys:

- FBAE 0323 821C 7706 A5CA 151B DCF5 13FA 7EED 19F3
- D630 0CAB CBF4 69BB E392 E503 A208 ED4F 8AF5 8446
- 16E1 2866 B773 8C73 976A 5743 6FCC 3343 9B0D 04DF
- 990C 3D0E AC7C 275D C6B1 8436 EACA B90B 1963 EC2B

There is a PGP keyblock with these keys available on [https://dnsdist.org/_static/dnsdist-keyblock.asc](https://dnsdist.org/_static/dnsdist-keyblock.asc).

Older (1.0.x) releases can also be signed with one of the following keys:

- 1628 90D0 689D D12D D33E 4696 1C5E E990 D2E7 1575
- B76C D467 1C09 68BA A87D E61C E5E5 071B F2FF E1A7
- Untar the tarball and `cd` into the source directory
- Run `./configure`
- Run `make` or `gmake` (on BSD)

2.2.2 From git

To compile from git, these additional dependencies are required:

- GNU Autoconf
- GNU Automake
- Ragel

dnsdist source code lives in the PowerDNS git repository but is independent of PowerDNS.
2.2.3 OS Specific Instructions

None, really.

2.2.4 Build options

Our configure script provides a fair number of options with regard to which features should be enabled, as well as which libraries should be used. In addition to these options, more features can be disabled at compile-time by defining the following symbols:

- DISABLE_BUILTIN_HTML removes the built-in web pages
- DISABLE_Carbon for carbon support
- DISABLE_COMPLETION for completion support in the console
- DISABLE_DELAY_PIPE removes the ability to delay UDP responses
- DISABLE_DEPRECATED_DYNBLOCK for legacy dynamic blocks not using the new DynBlockRulesGroup interface
- DISABLE_DYNBLOCKS disables the new dynamic block interface
- DISABLE_ECS_ACTIONS to disable actions altering EDNS Client Subnet
- DISABLE_FALSE_SHARING_PADDING to disable the padding of atomic counters, which is inserted to prevent false sharing but increases the memory use significantly
- DISABLE_HASHED_CREDENTIALS to disable password-hashing support
- DISABLE_LUA_WEB_HANDLERS for custom Lua web handlers support
- DISABLE_OCSPP_STAPLING for OCSP stapling
- DISABLE_OPENSSL_ERROR_STRINGS to disable the loading of OpenSSL’s error strings, reducing the memory use at the cost of human-readable error messages
- DISABLE_NPN for Next Protocol Negotiation, superseded by ALPN
- DISABLE_PROMETHEUS for prometheus
- DISABLE_PROTOBUF for protocol-buffer support, including dnstap
- DISABLE_RECVMSG for recvmsg support
- DISABLE_RULES_ALTERING_QUESTIONS to remove rules altering the content of queries
- DISABLE_SECPOLL for security polling
- DISABLE_WEB_CACHE_MANAGEMENT to disable cache management via the API
- DISABLE_WEB_CONFIG to disable accessing the configuration via the web interface

Additionally several Lua bindings can be removed when they are not needed, as they increase the memory required during compilation and the size of the final binary:

- DISABLE_CLIENT_STATE_BINDINGS
- DISABLE_COMBO_ADDR_BINDINGS
- DISABLE_DNSHEADER_BINDINGS
• DISABLE_DNSNAME_BINDINGS
• DISABLE_DOWNSTREAM_BINDINGS
• DISABLE_NETMASK_BINDINGS
• DISABLE_NON_FFI_DQ_BINDINGS
• DISABLE_PACKETCACHE_BINDINGS
• DISABLE_POLICIES_BINDINGS
• DISABLE_QPS_LIMITER_BINDINGS
• DISABLE_SUFFIX_MATCH_BINDINGS
• DISABLE_TOP_N_BINDINGS

Finally a build flag can be used to make use a single thread to handle all incoming UDP queries from clients, no matter how many `addLocal()` directives are present in the configuration. It also moves the task of accepting incoming TCP connections to the TCP workers themselves, removing the TCP acceptor threads. This option is destined to resource-constrained environments where dnsdist needs to listen on several addresses, over several interfaces, and one thread is enough to handle the traffic and therefore the overhead of using multiples threads for that task does not make sense. This option can be enabled by setting `USE_SINGLE_ACCEPTOR_THREAD`. 
This guide gives an overview of dnsdist features and operations.

### 3.1 Running in the Foreground

After *installing* dnsdist, the quickest way to start experimenting is launching it on the foreground with:

```
dnsdist -l 127.0.0.1:5300 9.9.9.9 2620:fe::fe 2620:fe::9
```

This will make dnsdist listen on IP address 127.0.0.1, port 5300 and forward all queries to the three listed IP addresses, with a sensible balancing policy.

### 3.2 dnsdist Console and Configuration

Here is more complete configuration, save it to `dnsdist.conf`:

```plaintext
newServer({address="2001:db8::1", qps=1})
newServer({address="2001:db8::2", qps=1})
newServer({address="[2001:db8::3]:5300", qps=10})
newServer({address="2001:db8::4", name="dns1", qps=10})
newServer("192.0.2.1")
setServerPolicy(firstAvailable) -- first server within its QPS limit
```

The `newServer()` function is used to add a backend server to the configuration.

Now run dnsdist again, reading this configuration:

```
$ dnsdist -C dnsdist.conf --local=0.0.0.0:5300
```

You can now send queries to port 5300, and get answers:

```
$ dig -t aaaa powerdns.com @127.0.0.1 -p 5300 +short +nocompile
2001:888:2000:1d::2
```

Note that dnsdist dropped us in a prompt above, where we can get some statistics:
showServers() is usually one of the first commands you will use when logging into the console. More advanced topics are covered in Working with the dnsdist Console.

Here we also see our configuration. 5 downstream servers have been configured, of which the first 4 have a QPS limit (of 1, 1, 10 and 10 queries per second, respectively).

The final server has no limit, which we can easily test:

```bash
$ for a in {0..1000}; do dig powerdns.com @127.0.0.1 -p 5300 +noall +nocookie > /dev/null; done
```

Note that the first 4 servers were all limited to near their configured QPS, and that our final server was taking up most of the traffic. No queries were dropped, and all servers remain up.

### 3.2.1 Changing Server Settings

The servers from showServers() are numbered, `getServer()` is used to get this Server object to manipulate it.

To force a server down, try `Server:setDown()`:

```bash
> getServer(0):setDown()
> showServers()
```

The `DOWN` in all caps means it was forced down. A lower case `down` would’ve meant that dnsdist itself had concluded the server was down. Similarly, `Server:setUp()` forces a server to be up, and `Server:setAuto()` returns it to the default availability-probing.
To change the QPS for a server, use `Server:setQPS()`:

```plaintext
> getServer(0):setQPS(1000)
```

### 3.3 Restricting Access

By default, dnsdist listens on `127.0.0.1` (not `::1`!), port 53.

To listen on a different address, use the `-l` command line option (useful for testing in the foreground), or use `setLocal()` and `addLocal()` in the configuration file:

```plaintext
setLocal('192.0.2.53') -- Listen on 192.0.2.53, port 53
addLocal('::1:5300') -- Also listen on ::1, port 5300
```

Before packets are processed they have to pass the ACL, which helpfully defaults to RFC 1918 private IP space. This prevents us from easily becoming an open DNS resolver.

Adding network ranges to the ACL is done with the `setACL()` and `addACL()` functions:

```plaintext
setACL({'192.0.2.0/28', '2001:db8:1::/56'}) -- Set the ACL to only allow these subnets
addACL('2001:db8:2::/56') -- Add this subnet to the existing ACL
```

### 3.4 Securing the path to the backend

dnsdist has always been designed as a load-balancer placed in front of authoritative or recursive servers, assuming that the network path between dnsdist and these servers is trusted.

If dnsdist is instead intended to be deployed in such a way that the path to its backend is not secure, the UDP protocol should not be used, and ‘TCP-only’, DNS over TLS and DNS over HTTPS protocols used instead, as supported since 1.7.0.

For more details, please look at the Configuring Downstream Servers guide.

### 3.5 More Information

Following this quickstart guide allowed you to set up a basic balancing dnsdist instance. However, dnsdist is much more powerful. See the Guides and/or the Advanced Topics sections on how to shape, shut and otherwise manipulate DNS traffic.
CHAPTER
FOUR

RUNNING AND CONFIGURING DNSDIST

dnsdist is meant to run as a daemon. As such, distribution native packages know how to stop/start themselves using operating system services.

It is configured with a configuration file called dnsdist.conf The default path to this file is determined by the SYSCONFDIR variable during compilation. Most likely this path is /etc/dnsdist, /etc or /usr/local/etc, dnsdist will tell you on startup which file it reads.

dnsdist is designed to (re)start almost instantly. But to prevent downtime when changing configuration, the console (see Working with the dnsdist Console) can be used for live configuration.

Issuing delta() on the console will print the changes to the configuration that have been made since startup:

```
> delta()
-- Wed Feb 22 2017 11:31:44 CET
addLocal('127.0.0.1:5301', false)
-- Wed Feb 22 2017 12:03:48 CET
addACL('192.0.2.1/8')
-- Wed Feb 22 2017 12:05:51 CET
addACL('2001:db8::1')
```

These commands can be copied to the configuration file, should they need to persist after a restart.

4.1 Running as unprivileged user

dnsdist can drop privileges using the --uid and --gid command line switches to ensure it does not run with root privileges. Note that dnsdist drops its privileges after parsing its startup configuration and binding its listening and initial newServer() sockets as user root. It is highly recommended to create a system user and group for dnsdist. Note that most packaged versions of dnsdist already create this user.

4.2 Understanding how queries are forwarded to backends

Initially dnsdist tried to forward a query to the backend using the same protocol than the client used to contact dnsdist: queries received over UDP were forwarded over UDP, and the same for TCP. When incoming DNSCrypt and DNS over TLS support were added, the same logic was applied, so DoT queries are forwarded over TCP. For DNS over HTTPS, UDP was selected instead for performance reason, breaking with the existing logic.

Before 1.7.0, which introduced TCP fallback, that meant that there was a potential issue with very large answers and DNS over HTTPS, requiring careful configuration of the path between dnsdist and the backend. More information about that is available in the DNS over HTTPS section.

In addition to TCP fallback for DoH, 1.7.0 introduced three new notions:

- TCP-only backends, for which queries will always forwarded over a TCP connection (see the tcpOnly parameter of newServer())
• DNS over HTTPS backends, for which queries are forwarded over a DNS over HTTPS connection (see the `dohPath` parameter of `newServer()`)

• and DNS over TLS backends, for which queries are forwarded over a DNS over TLS connection (see the `tls` parameter of `newServer()`)

To sum it up:

<table>
<thead>
<tr>
<th>Incoming</th>
<th>Outgoing (regular)</th>
<th>Outgoing (TCP-only, 1.7+)</th>
<th>Outgoing (TLS, 1.7+)</th>
<th>Outgoing (DoH, 1.7+)</th>
</tr>
</thead>

</tbody>
</table>
**dnsdist** works in essence like any other loadbalancer:

It receives packets on one or several addresses it listens on, and determines whether it will process this packet based on the *Access Control*. Should the packet be processed, **dnsdist** attempts to match any of the configured rules in order and when one matches, the associated action is performed.

These rule and action combinations are considered policies.

### 5.1 Packet Actions

Each packet can be:

- Dropped
- Turned into an answer directly
- Forwarded to a downstream server
- Modified and forwarded to a downstream and be modified back
- Be delayed

This decision can be taken at different times during the forwarding process. All packets not handled by an explicit action are forwarded to a downstream server in the default pool.

#### 5.1.1 Examples

**Rules for traffic exceeding QPS limits**

Traffic that exceeds a QPS limit, in total or per IP (subnet) can be matched by a rule.

For example:

```plaintext
addAction(MaxQPSIPRule(5, 32, 48), DelayAction(100))
```

This measures traffic per IPv4 address and per /48 of IPv6, and if traffic for such an address (range) exceeds 5 qps, it gets delayed by 100ms. (Please note: *DelayAction()* can only delay UDP traffic).

As another example:

```plaintext
addAction(MaxQPSIPRule(5), SetNoRecurseAction())
```

This strips the Recursion Desired (RD) bit from any traffic per IPv4 or IPv6 /64 that exceeds 5 qps. This means any those traffic bins is allowed to make a recursor do ‘work’ for only 5 qps.

If this is not enough, try:

```plaintext
addAction(MaxQPSIPRule(5), DropAction())
```
or:
```
addAction(AndRule{MaxQPSIPRule(5), TCPRule(false)}, TCAction())
```

This will respectively drop traffic exceeding that 5 QPS limit per IP or range, or return it with TC=1, forcing clients to fall back to TCP.

In that last one, note the use of `TCPRule()`. Without it, clients would get TC=1 even if they correctly fell back to TCP.

To turn this per IP or range limit into a global limit, use `NotRule(MaxQPSRule(5000))` instead of `MaxQPSIPRule()`.

**Regular Expressions**

`RegexRule()` matches a regular expression on the query name, and it works like this:
```
addAction(RegexRule("[0-9]{5,}"), DelayAction(750)) -- milliseconds
addAction(RegexRule("[0-9]{4,}\..example$"), DropAction())
```

This delays any query for a domain name with 5 or more consecutive digits in it. The second rule drops anything with more than 4 consecutive digits within a .example domain.

Note that the query name is presented without a trailing dot to the regex. The regex is applied case insensitively.

Alternatively, if compiled in, `RE2Rule()` provides similar functionality, but against libre2.

Note that to check if a name is in a list of domains, `QNameSuffixRule()` is preferred over complex regular expressions or multiple instances of `RegexRule()`.

### 5.2 Rule Generators

**dnsdist** contains several functions that make it easier to add actions and rules.

#### `addLuaAction` (`DNSrule`, `function[, options]`)

Deprecated since version 1.4.0: Removed in 1.4.0, use `LuaAction()` with `addAction()` instead.

Invoke a Lua function that accepts a `DNSQuestion`. This function works similar to using `LuaAction()`. The function should return both a `DNSAction` and its argument `rule`. The `rule` is used as an argument of the following `DNSAction`: `DNSAction.Spoof`, `DNSAction.Pool` and `DNSAction.Delay`. If the Lua code fails, ServFail is returned.

**Parameters**

- `DNSRule` – match queries based on this rule
- `function(string)` – the name of a Lua function
- `options` (table) – A table with key: value pairs with options.

**Options:**

- `uuid`: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.

```lua
function luaaction(dq)
    if (dq.qtype==DNSQType.NAPTR) then
        return DNSAction.Pool, "abuse" -- send to abuse pool
    else
        return DNSAction.None, "" -- no action
        -- `DNSAction.None`  -- as of dnsdist version 1.3.0
    end
end
```

(continues on next page)
addLuaAction(AllRule(), luaaction)

addLuaResponseAction(DNSrule, function[, options])
Deprecated since version 1.4.0: Removed in 1.4.0, use LuaResponseAction() with addResponseAction() instead.

Invoke a Lua function that accepts a DNSResponse. This function works similar to using LuaResponseAction(). The function should return both a DNSResponseAction and its argument rule. The rule is used as an argument of the DNSResponseAction.Delay. If the Lua code fails, ServFail is returned.

Parameters

• DNSRule – match queries based on this rule
• function(string) – the name of a Lua function
• options(table) – A table with key: value pairs with options.

Options:

• uuid: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.

5.3 Managing Rules

Active Rules can be shown with showRules() and removed with rmRule():

<table>
<thead>
<tr>
<th>#</th>
<th>Matches Rule</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>h4xorbooter.xyz.</td>
<td>qps limit to 10</td>
</tr>
<tr>
<td>1</td>
<td>130.161.0.0/16, 145.14.0.0/16</td>
<td>qps limit to 20</td>
</tr>
<tr>
<td>2</td>
<td>nl., be.</td>
<td>qps limit to 1</td>
</tr>
</tbody>
</table>

For Rules related to the incoming query:

addAction(DNSrule, action[, options])

Changed in version 1.6.0: Added name to the options.

Changed in version 1.9.0: Passing a string or list of strings instead of a DNSRule is deprecated, use NetmaskGroupRule() or QNameSuffixRule() instead

Add a Rule and Action to the existing rules. If a string (or list of) is passed as the first parameter instead of a DNSRule, it behaves as if the string or list of strings was passed to NetmaskGroupRule() or SuffixMatchNodeRule().

Parameters

• rule(DNSrule) – A DNSRule, e.g. an AllRule(), or a compounded bunch of rules using e.g. AndRule(). Before 1.9.0 it was also possible to pass a string (or list of strings) but doing so is now deprecated.

• action – The action to take

• options(table) – A table with key: value pairs with options.

Options:

• uuid: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.
• name: string - Name to assign to the new rule.

5.3. Managing Rules
clearRules()
Remove all current rules.

getAction(n) → DNSDistRuleAction
Returns the DNSDistRuleAction associated with rule n.

Parameters

n (int) – The rule number

getCacheHitResponseRule(selector) → DNSDistResponseRuleAction
New in version 1.9.0.
Return the cache-hit response rule corresponding to the selector, if any. The selector can be the position of the rule in the list, as an integer, its name as a string or its UUID as a string as well.

Parameters

or str selector (int) – The position in the list, name or UUID of the rule to return.

getCacheInsertedResponseRule(selector) → DNSDistResponseRuleAction
New in version 1.9.0.
Return the cache-inserted response rule corresponding to the selector, if any. The selector can be the position of the rule in the list, as an integer, its name as a string or its UUID as a string as well.

Parameters

or str selector (int) – The position in the list, name or UUID of the rule to return.

getResponseRule(selector) → DNSDistResponseRuleAction
New in version 1.9.0.
Return the response rule corresponding to the selector, if any. The selector can be the position of the rule in the list, as an integer, its name as a string or its UUID as a string as well.

Parameters

or str selector (int) – The position in the list, name or UUID of the rule to return.

getRule(selector) → DNSDistRuleAction
New in version 1.9.0.
Return the rule corresponding to the selector, if any. The selector can be the position of the rule in the list, as an integer, its name as a string or its UUID as a string as well.

Parameters

or str selector (int) – The position in the list, name or UUID of the rule to return.

getSelfAnsweredResponseRule(selector) → DNSDistResponseRuleAction
New in version 1.9.0.
Return the self-answered response rule corresponding to the selector, if any. The selector can be the position of the rule in the list, as an integer, its name as a string or its UUID as a string as well.

Parameters

or str selector (int) – The position in the list, name or UUID of the rule to return.

mvRule(from, to)
Move rule from to a position where it is in front of to. to can be one larger than the largest rule, in which case the rule will be moved to the last position.

Parameters

• from (int) – Rule number to move
• to (int) – Location to move the Rule to

topRule()
New in version 1.6.0.
This function moves the last rule to the first position. Before 1.6.0 this was handled by topRule().
newRuleAction (rule, action[, options])

Changed in version 1.6.0: Added name to the options.

Return a pair of DNS Rule and DNS Action, to be used with setRules().

Parameters

- rule (Rule) – A Rule (see Matching Packets (Selectors))
- action (Action) – The Action (see Actions) to apply to the matched traffic
- options (table) – A table with key: value pairs with options.

Options:

- uuid: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.
- name: string - Name to assign to the new rule.

setRules (rules)

Replace the current rules with the supplied list of pairs of DNS Rules and DNS Actions (see newRuleAction())

Parameters rules ([RuleAction]) – A list of RuleActions

showRules ([]) –

Show all defined rules for queries, optionally displaying their UUIDs.

Parameters options (table) – A table with key: value pairs with display options.

Options:

- showUUIDs=false: bool - Whether to display the UUIDs, defaults to false.
- truncateRuleWidth=-1: int - Truncate rules output to truncateRuleWidth size. Defaults to -1 to display the full rule.

topRule ()

Changed in version 1.6.0: Replaced by mvRuleToTop()

Before 1.6.0 this function used to move the last rule to the first position, which is now handled by mvRuleToTop().

rmRule (id)

Changed in version 1.6.0: id can now be a string representing the name of the rule.

Remove rule id.

Parameters id (int) – The position of the rule to remove if id is numerical, its UUID or name otherwise

For Rules related to responses:

addResponseAction (DNSRule, action[, options])

Changed in version 1.6.0: Added name to the options.

Changed in version 1.9.0: Passing a string or list of strings instead of a DNSRule is deprecated, use NetmaskGroupRule() or QNameSuffixRule() instead

Add a Rule and Action for responses to the existing rules. If a string (or list of) is passed as the first parameter instead of a DNSRule, it behaves as if the string or list of strings was passed to NetmaskGroupRule() or SuffixMatchNodeRule() instead.

Parameters

- rule (DNSrule) – A DNSRule, e.g. an AllRule(), or a compounded bunch of rules using e.g. AndRule(). Before 1.9.0 it was also possible to pass a string (or list of strings) but doing so is now deprecated.
- action – The action to take
- options (table) – A table with key: value pairs with options.
Options:

- **uuid**: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.
- **name**: string - Name to assign to the new rule.

**mvResponseRule (from, to)**

Move response rule _from_ to a position where it is in front of _to_. _to_ can be one larger than the largest rule, in which case the rule will be moved to the last position.

**Parameters**

- **from** _int_ – Rule number to move
- **to** _int_ – Location to move the Rule to

**mvResponseRuleToTop()**

New in version 1.6.0.

This function moves the last response rule to the first position. Before 1.6.0 this was handled by `topResponseRule()`.

**rmResponseRule (id)**

Changed in version 1.6.0: _id_ can now be a string representing the name of the rule.

Remove response rule _id_.

**Parameters**

- **id** _int_ – The position of the rule to remove if _id_ is numerical, its UUID or name otherwise

**showResponseRules ([options])**

Show all defined response rules, optionally displaying their UUIDs.

**Parameters**

- **options** _table_ – A table with key: value pairs with display options.

**topResponseRule()**

Changed in version 1.6.0: Replaced by `mvResponseRuleToTop()`.

Before 1.6.0 this function used to move the last response rule to the first position, which is now handled by `mvResponseRuleToTop()`.

Functions for manipulating Cache Hit Response Rules:

**addCacheHitResponseAction (DNSRule, action[, options])**

Changed in version 1.6.0: Added `name` to the options.

Changed in version 1.9.0: Passing a string or list of strings instead of a `DNSRule` is deprecated, use `NetmaskGroupRule()` or `QNameSuffixRule()` instead.

Add a Rule and ResponseAction for Cache Hits to the existing rules. If a string (or list of) is passed as the first parameter instead of a `DNSRule`, it behaves as if the string or list of strings was passed to `NetmaskGroupRule()` or `SuffixMatchNodeRule()`.

**Parameters**

- **rule** _DNSrule_ – A `DNSRule`, e.g. an `AllRule()`, or a compounded bunch of rules using e.g. `AndRule()`. Before 1.9.0 it was also possible to pass a string (or list of strings) but doing so is now deprecated.
- **action** – The action to take
- **options** _table_ – A table with key: value pairs with options.

**Options:**
• **uuid**: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.

• **name**: string - Name to assign to the new rule.

**mvCacheHitResponseRule**(from, to)
Move cache hit response rule from to a position where it is in front of to. to can be one larger than the largest rule, in which case the rule will be moved to the last position.

**Parameters**

- **from**(int) – Rule number to move
- **to**(int) – Location to more the Rule to

**mvCacheHitResponseRuleToTop()**
New in version 1.6.0.
This function moves the last cache hit response rule to the first position. Before 1.6.0 this was handled by **topCacheHitResponseRule().**

**rmCacheHitResponseRule**(id)
Changed in version 1.6.0: id can now be a string representing the name of the rule.

**Parameters**

- **id**(int) – The position of the rule to remove if id is numerical, its UUID or name otherwise

**showCacheHitResponseRules**(options)
Show all defined cache hit response rules, optionally displaying their UUIDs.

**Parameters**

- **options**(table) – A table with key: value pairs with display options.

**Options:**

- **showUUIDs=false**(bool) - Whether to display the UUIDs, defaults to false.
- **truncateRuleWidth=-1**(int) - Truncate rules output to truncateRuleWidth size. Defaults to -1 to display the full rule.

**topCacheHitResponseRule()**
Changed in version 1.6.0: Replaced by **mvCacheHitResponseRuleToTop()**
Before 1.6.0 this function used to move the last cache hit response rule to the first position, which is now handled by **mvCacheHitResponseRuleToTop().**

Functions for manipulating Cache Inserted Response Rules:

**addCacheInsertedResponseAction**(DNSRule, action[], options)
New in version 1.8.0.

Changed in version 1.9.0: Passing a string or list of strings instead of a **DNSRule** is deprecated, use **NetmaskGroupRule()** or **QNameSuffixRule()** instead

Add a Rule and ResponseAction that is executed after a cache entry has been inserted to the existing rules.
If a string (or list of) is passed as the first parameter instead of a **DNSRule**, it behaves as if the string or list of strings was passed to **NetmaskGroupRule()** or **SuffixMatchNodeRule().**

**Parameters**

- **rule**(DNSrule) – A **DNSRule**, e.g. an **AllRule()**, or a compounded bunch of rules using e.g. **AndRule().** Before 1.9.0 it was also possible to pass a string (or list of strings) but doing so is now deprecated.
- **action** – The action to take
- **options**(table) – A table with key: value pairs with options.

**Options:**

- **uuid**: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.
- **name**: string - Name to assign to the new rule.
dnsdist

mvCacheInsertedResponseRule (from, to)
New in version 1.8.0.
Move cache inserted response rule from to a position where it is in front of to. to can be one larger than
the largest rule, in which case the rule will be moved to the last position.

Parameters
• from (int) – Rule number to move
• to (int) – Location to move the Rule to

mvCacheInsertedResponseRuleToTop()
New in version 1.8.0.
This function moves the last cache inserted response rule to the first position.

rmCacheInsertedResponseRule (id)
New in version 1.8.0.

Parameters
id (int) – The position of the rule to remove if id is numerical, its UUID or
name otherwise

showCacheInsertedResponseRules ([options])
New in version 1.8.0.
Show all defined cache inserted response rules, optionally displaying their UUIDs.

Parameters
options (table) – A table with key: value pairs with display options.

Options:
• showUUIDs=false: bool - Whether to display the UUIDs, defaults to false.
• truncateRuleWidth=-1: int - Truncate rules output to truncateRuleWidth size. Defaults
to -1 to display the full rule.

Functions for manipulating Self-Answered Response Rules:

addSelfAnsweredResponseAction (DNSRule, action [, options ]) Changed in version 1.6.0: Added name to the options.

Changed in version 1.9.0: Passing a string or list of strings instead of a DNSRule is deprecated, use
NetmaskGroupRule() or QNameSuffixRule() instead

Add a Rule and Action for Self-Answered queries to the existing rules. If a string (or list of) is passed
as the first parameter instead of a DNSRule, it behaves as if the string or list of strings was passed to
NetmaskGroupRule() or QNameSuffixRule().

Parameters
• rule (DNSrule) – A DNSRule, e.g. an AllRule(), or a compounded bunch of
rules using e.g. AndRule(). Before 1.9.0 it was also possible to pass a string (or list
of strings) but doing so is now deprecated.
• action – The action to take
• options (table) – A table with key: value pairs with options.

Options:
• uuid: string - UUID to assign to the new rule. By default a random UUID is generated for each rule.
• name: string - Name to assign to the new rule.

mvSelfAnsweredResponseRule (from, to)
Move self answered response rule from to a position where it is in front of to. to can be one larger than
the largest rule, in which case the rule will be moved to the last position.

Parameters
• from (int) – Rule number to move
**to** (int) – Location to more the Rule to

**mvSelfAnsweredResponseRuleToTop**
New in version 1.6.0.

This function moves the last self-answered response rule to the first position. Before 1.6.0 this was handled by **topSelfAnsweredResponseRule**.

**rmSelfAnsweredResponseRule** (*id*)
Changed in version 1.6.0: *id* can now be a string representing the name of the rule.

Remove self answered response rule *id*.

**Parameters**
- **id** (int) – The position of the rule to remove if *id* is numerical, its UUID or name otherwise

**showSelfAnsweredResponseRules** ([**options**])
Show all defined self answered response rules, optionally displaying their UUIDs.

**Parameters**
- **options** (*table*) – A table with key: value pairs with display options.

**Options**:
- **showUUIDs=false**: bool - Whether to display the UUIDs, defaults to false.
- **truncateRuleWidth=-1**: int - Truncate rules output to **truncateRuleWidth** size. Defaults to -1 to display the full rule.

**topSelfAnsweredResponseRule**
Changed in version 1.6.0: Replaced by **mvSelfAnsweredResponseRuleToTop**.

Before 1.6.0 this function used to move the last cache hit response rule to the first position, which is now handled by **mvSelfAnsweredResponseRuleToTop**.

Move the last self answered response rule to the first position.

### 5.4 Matching Packets (Selectors)

Packets can be matched by selectors, called a DNSRule. These DNSRules be one of the following items:

- A string that is either a domain name or netmask
- A list of strings that are either domain names or netmasks
- A DNSName
- A list of DNSNames
- A (compounded) Rule

**AllRule**
Matches all traffic

**DNSSECRule**
Matches queries with the DO flag set

**DSTPortRule** (*port*)
Matches questions received to the destination port.

**Parameters**
- **port** (int) – Match destination port.

**EDNSOptionRule** (*optcode*)
New in version 1.4.0.

Matches queries or responses with the specified EDNS option present. *optcode* is specified as an integer, or a constant such as **EDNSOptionCode.ECS**.
EDNSVersionRule \((version)\)

New in version 1.4.0.

Matches queries or responses with an OPT record whose EDNS version is greater than the specified EDNS version.

**Parameters**

- **version** \((int)\) – The EDNS version to match on

ERCodeRule \((rcode)\)

Matches queries or responses with the specified rcode. rcode can be specified as an integer or as one of the built-in RCode. The full 16bit RCode will be matched. If no EDNS OPT RR is present, the upper 12 bits are treated as 0.

**Parameters**

- **rcode** \((int)\) – The RCODE to match on

HTTPHeaderRule \((name, regex)\)

New in version 1.4.0.

Changed in version 1.8.0: see keepIncomingHeaders on addDOHLocal()

Matches DNS over HTTPS queries with a HTTP header name whose content matches the regular expression regex. Since 1.8.0 it is necessary to set the keepIncomingHeaders option to true on addDOHLocal() to be able to use this rule.

**Parameters**

- **name** \((str)\) – The case-insensitive name of the HTTP header to match on
- **regex** \((str)\) – A regular expression to match the content of the specified header

HTTPPathRegexRule \((regex)\)

New in version 1.4.0.

Matches DNS over HTTPS queries with a HTTP path matching the regular expression supplied in regex. For example, if the query has been sent to the https://192.0.2.1:443/PowerDNS?dns=... URL, the path would be ‘/PowerDNS’. Only valid DNS over HTTPS queries are matched. If you want to match all HTTP queries, see DOHFrontend:setResponsesMap() instead.

**Parameters**

- **regex** \((str)\) – The regex to match on

HTTPPathRule \((path)\)

New in version 1.4.0.

Matches DNS over HTTPS queries with a HTTP path of path. For example, if the query has been sent to the https://192.0.2.1:443/PowerDNS?dns=... URL, the path would be ‘/PowerDNS’. Only valid DNS over HTTPS queries are matched. If you want to match all HTTP queries, see DOHFrontend:setResponsesMap() instead.

**Parameters**

- **path** \((str)\) – The exact HTTP path to match on

KeyValueStoreLookupRule \((kvs, lookupKey)\)

New in version 1.4.0.

Return true if the key returned by ‘lookupKey’ exists in the key value store referenced by ‘kvs’. The store can be a CDB \(\text{newCDBKVStore}()\) or a LMDB database \(\text{newLMDBKVStore}()\). The key can be based on the qname \(\text{KeyValueLookupKeyQName}()\) and \(\text{KeyValueLookupKeySuffix}()\), source IP \(\text{KeyValueLookupKeySourceIP}()\) or the value of an existing tag \(\text{KeyValueLookupKeyTag}()\).

**Parameters**

- **kvs** \((\text{KeyValueStore})\) – The key value store to query
- **lookupKey** \((\text{KeyValueLookupKey})\) – The key to use for the lookup

KeyValueStoreRangeLookupRule \((kvs, lookupKey)\)

New in version 1.7.0.

Does a range-based lookup into the key value store referenced by ‘kvs’ using the key returned by ‘lookupKey’ and returns true if there is a range covering that key.
This assumes that there is a key, in network byte order, for the last element of the range (for example 2001:0db8:ffff:ffff:ffff:ffff:ffff:ffff for 2001:db8::/32) which contains the first element of the range (2001:0db8:0000:0000:0000:0000:0000:0000) (optionally followed by any data) as value, still in network byte order, and that there is no overlapping ranges in the database. This requires that the underlying store supports ordered keys, which is true for LMDB but not for CDB.

**Parameters**

- `kvs (KeyValueStore)` – The key value store to query
- `lookupKey (KeyValueLookupKey)` – The key to use for the lookup

**LuaFFIPerThreadRule (function)**

New in version 1.7.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return true if the query matches, or false otherwise. If the Lua code fails, false is returned.

The function will be invoked in a per-thread Lua state, without access to the global Lua state. All constants (DNSQType, RCode, ...) are available in that per-thread context, as well as all FFI functions. Objects and their bindings that are not usable in a FFI context (DNSQuestion, DNSDistProtoBufMessage, PacketCache, ...) are not available.

**Parameters**

- `function (string)` – a Lua string returning a Lua function

**LuaFFIRule (function)**

New in version 1.5.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return true if the query matches, or false otherwise. If the Lua code fails, false is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**LuaRule (function)**

New in version 1.5.0.

Invoke a Lua function that accepts a `DNSQuestion` object.

The function should return true if the query matches, or false otherwise. If the Lua code fails, false is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**MaxQPSIPRule (qps[, v4Mask[, v6Mask[, burst[, expiration[, cleanupDelay[, scanFraction[, shards]]]]]]])**

Changed in version 1.8.0: shards parameter added

Matches traffic for a subnet specified by v4Mask or v6Mask exceeding `qps` queries per second up to `burst` allowed. This rule keeps track of QPS by netmask or source IP. This state is cleaned up regularly if `cleanupDelay` is greater than zero, removing existing netmasks or IP addresses that have not been seen in the last `expiration` seconds.

**Parameters**

- `qps (int)` – The number of queries per second allowed, above this number traffic is matched
- `v4Mask (int)` – The IPv4 netmask to match on. Default is 32 (the whole address)
- `v6Mask (int)` – The IPv6 netmask to match on. Default is 64
- `burst (int)` – The number of burstable queries per second allowed. Default is same as `qps`
• **expiration (int)** – How long to keep netmask or IP addresses after they have last been seen, in seconds. Default is 300
• **cleanupDelay (int)** – The number of seconds between two cleanups. Default is 60
• **scanFraction (int)** – The maximum fraction of the store to scan for expired entries, for example 5 would scan at most 20% of it. Default is 10 so 10%
• **shards (int)** – How many shards to use, to decrease lock contention between threads. Default is 10 and is a safe default unless a very high number of threads are used to process incoming queries

**MaxQPSRule (qps)**

Matches traffic not exceeding this qps limit. If e.g. this is set to 50, starting at the 51st query of the current second traffic stops being matched. This can be used to enforce a global QPS limit.

**Parameters**

qps (int) – The number of queries per second allowed, above this number the traffic is not matched anymore

**NetmaskGroupRule (nmg[, src[, quiet]])**

Changed in version 1.4.0: quiet parameter added

Changed in version 1.9.0: The nmg parameter now accepts a string or a list of strings in addition to a class:NetmaskGroup object.

Matches traffic from/to the network range specified in the nmg, which can be a string, a list of strings, or a NetmaskGroup object created via newNMG().

Set the src parameter to false to match nmg against destination address instead of source address. This can be used to differentiate between clients

**Parameters**

• nmg (NetmaskGroup) – The netmasks to match, can be a string, a list of strings or a NetmaskGroup object.
• src (bool) – Whether to match source or destination address of the packet. Defaults to true (matches source)
• quiet (bool) – Do not display the list of matched netmasks in Rules. Default is false.

**OpcodeRule (code)**

Matches queries with opcode code. code can be directly specified as an integer, or one of the built-in DNSOpcodes.

**Parameters**

code (int) – The opcode to match

**PayloadSizeRule (comparison, size)**

New in version 1.9.0.

Matches queries or responses whose DNS payload size fits the given comparison.

**Parameters**

• comparison (str) – The comparison operator to use. Supported values are equal, greater, greaterOrEqual, smaller and smallerOrEqual.
• size (int) – The size to compare to.

**ProbaRule (probability)**

Matches queries with a given probability. 1.0 means “always”

**Parameters**

probability (double) – Probability of a match

**ProxyProtocolValueRule (type[, value])**

New in version 1.6.0.

Matches queries that have a proxy protocol TLV value of the specified type. If value is set, the content of the value should also match the content of value.

**Parameters**

...
• **type** *(int)* – The type of the value, ranging from 0 to 255 (both included)

• **value** *(str)* – The optional binary-safe value to match

**QClassRule** *(qclass)*
Matches queries with the specified *qclass*. *class* can be specified as an integer or as one of the built-in *DNSClass*.

**Parameters**
- **qclass** *(int)* – The Query Class to match on

**QNameRule** *(qname)*
Matches queries with the specified *qname* exactly.

**Parameters**
- **qname** *(string)* – *Qname* to match

**QNameSetRule** *(set)*
New in version 1.4.0: Matches if the set contains exact qname.

To match subdomain names, see **QNameSuffixRule**().

**Parameters**
- **set** – *DNSNameSet* with names of type class:*DNSNameSet* created with *newDNSNameSet()*.

**QNameSuffixRule** *(suffixes)*
New in version 1.9.0.

Matches based on a group of domain suffixes for rapid testing of membership. The first parameter, *suffixes*, can be a string, list of strings or a class:*SuffixMatchNode* object created with *newSuffixMatchNode()*. Pass true as second parameter to prevent listing of all domains matched.

To match domain names exactly, see **QNameSetRule**().

This rule existed before 1.9.0 but was called **SuffixMatchNodeRule**(), only accepting a *SuffixMatchNode* parameter.

**Parameters**
- **suffixes** – A string, list of strings, or a *SuffixMatchNode* to match on
- **quiet** *(bool)* – Do not display the list of matched domains in Rules. Default is false.

**QNameLabelsCountRule** *(min, max)*
Matches if the qname has less than *min* or more than *max* labels.

**Parameters**
- **min** *(int)* – Minimum number of labels
- **max** *(int)* – Maximum number of labels

**QNameWireLengthRule** *(min, max)*
Matches if the qname’s length on the wire is less than *min* or more than *max* bytes.

**Parameters**
- **min** *(int)* – Minimum number of bytes
- **max** *(int)* – Maximum number of bytes

**QTypeRule** *(qtype)*
Matches queries with the specified *qtype*. *qtype* may be specified as an integer or as one of the built-in *QTypes*. For instance *DNSQType.A*, *DNSQType.TXT* and *DNSQType.ANY*.

**Parameters**
- **qtype** *(int)* – The *QType* to match on

**RCodeRule** *(rcode)*
Matches queries or responses with the specified *rcode*. *rcode* can be specified as an integer or as one of the built-in *RCodes*. Only the non-extended RCode is matched (lower 4bits).
**Parameters** \texttt{rcode (int)} – The RCODE to match on

**RDRule ()**
Matches queries with the RD flag set.

**RegexRule (regex)**
Matches the query name against the regex.

```python
addAction(RegexRule("[0-9]{5,}"), DelayAction(750)) -- milliseconds
addAction(RegexRule("[0-9]{4,}\.[\text{example}]$"), DropAction())
```

This delays any query for a domain name with 5 or more consecutive digits in it. The second rule drops anything with more than 4 consecutive digits within a .EXAMPLE domain.

Note that the query name is presented without a trailing dot to the regex. The regex is applied case insensitively.

**Parameters** \texttt{regex (string)} – A regular expression to match the traffic on

**RecordsCountRule (section, minCount, maxCount)**
Matches if there is at least \texttt{minCount} and at most \texttt{maxCount} records in the section \texttt{section}. \texttt{section} can be specified as an integer or as a \texttt{DNS Packet Sections}.

**Parameters**
- \texttt{section (int)} – The section to match on
- \texttt{minCount (int)} – The minimum number of entries
- \texttt{maxCount (int)} – The maximum number of entries

**RecordsTypeCountRule (section, qtype, minCount, maxCount)**
Matches if there is at least \texttt{minCount} and at most \texttt{maxCount} records of type \texttt{qtype} in the section \texttt{section}. \texttt{section} can be specified as an integer or as a \texttt{DNS Packet Sections}. \texttt{qtype} may be specified as an integer or as one of the \texttt{built-in QTypes}, for instance \texttt{DNSQType.A} or \texttt{DNSQType.TXT}.

**Parameters**
- \texttt{section (int)} – The section to match on
- \texttt{qtype (int)} – The QTYPE to match on
- \texttt{minCount (int)} – The minimum number of entries
- \texttt{maxCount (int)} – The maximum number of entries

**RE2Rule (regex)**
Matches the query name against the supplied regex using the RE2 engine.

For an example of usage, see \texttt{RegexRule()}.  

**Note** Only available when \texttt{dnsdist} was built with libre2 support.

**Parameters** \texttt{regex (str)} – The regular expression to match the QNAME.

**SNIRule (name)**
New in version 1.4.0.

Matches against the TLS Server Name Indication value sent by the client, if any. Only makes sense for DoT or DoH, and for that last one matching on the HTTP Host header using \texttt{HTTPHeaderRule()} might provide more consistent results. As of the version 2.3.0-beta of h2o, it is unfortunately not possible to extract the SNI value from DoH connections, and it is therefore necessary to use the HTTP Host header until version 2.3.0 is released, or \texttt{nghttp2} is used for incoming DoH instead (1.9.0+).

**Parameters** \texttt{name (str)} – The exact SNI name to match.

**SuffixMatchNodeRule (smn, quiet)**
Changed in version 1.9.0: The \texttt{smn} parameter now accepts a string or a list of strings in addition to a class:SuffixMatchNode object.
Matches based on a group of domain suffixes for rapid testing of membership. The first parameter, smn, can be a string, list of strings or a class: `SuffixMatchNode` object created with `newSuffixMatchNode()`. Pass true as second parameter to prevent listing of all domains matched.

To match domain names exactly, see `QNameSetRule()`.

Since 1.9.0, this rule can also be used via the alias `QNameSuffixRule()`.

**Parameters**

- **smn** (`SuffixMatchNode`) — A string, list of strings, or a `SuffixMatchNode` to match on
- **quiet** (`bool`) — Do not display the list of matched domains in Rules. Default is false.

**TagRule** (`name[, value]`)

Matches question or answer with a tag named `name` set. If `value` is specified, the existing tag value should match too.

**Parameters**

- **name** (`string`) — The name of the tag that has to be set
- **value** (`string`) — If set, the value the tag has to be set to. Default is unset

**TCPRule** (`tcp`)

Matches question received over TCP if `tcp` is true, over UDP otherwise.

**Parameters**

- **tcp** (`bool`) — Match TCP traffic if true, UDP traffic if false.

**TrailingDataRule** ()

Matches if the query has trailing data.

**PoolAvailableRule** (`poolname`)

Check whether a pool has any servers available to handle queries

```latex
--- Send queries to default pool when servers are available
addAction(PoolAvailableRule(""), PoolAction(""))
--- Send queries to fallback pool if not
addAction(AllRule(), PoolAction("fallback"))
```

**Parameters**

- **poolname** (`string`) — Pool to check

**PoolOutstandingRule** (`poolname, limit`)

New in version 1.7.0.

Check whether a pool has total outstanding queries above limit

```latex
--- Send queries to spill over pool if default pool is under pressure
addAction(PoolOutstandingRule("", 5000), PoolAction("spillover"))
```

**Parameters**

- **poolname** (`string`) — Pool to check
- **limit** (`int`) — Total outstanding limit

### 5.4.1 Combining Rules

**AndRule** (`selectors`)

Matches traffic if all `selectors` match.

**Parameters**

- **selectors** (`{Rule}`) — A table of Rules

**NotRule** (`selector`)

Matches the traffic if the `selector` rule does not match;

---

5.4. Matching Packets (Selectors)
Parameters **selector** *(Rule)* – A Rule

**OrRule** *(selectors)*

Matches the traffic if one or more of the selectors Rules does match.

Parameters **selector** *(Rule)* – A table of Rules

### 5.4.2 Convenience Functions

**makeRule** *(rule)*

Changed in version 1.9.0: This function is deprecated, please use *NetmaskGroupRule()* or *QnameSuffixRule()* instead

Make a *NetmaskGroupRule()* or a *SuffixMatchNodeRule()*, depending on how it is called. The *rule* parameter can be a string, or a list of strings, that should contain either:

- netmasks: in which case it will behave as *NetmaskGroupRule()*.
- domain names: in which case it will behave as *SuffixMatchNodeRule()*

Mixing both netmasks and domain names is not supported, and will result in domain names being ignored!

*makeRule*("0.0.0.0/0") will for example match all IPv4 traffic, *makeRule*({"be","nl", "lu"}) will match all Benelux DNS traffic.

Parameters **rule** *(string)* – A string, or list of strings, to convert to a rule.

### 5.5 Actions

Matching Packets (Selectors) need to be combined with an action for them to actually do something with the matched packets. Some actions allow further processing of rules, this is noted in their description. Most of these start with 'Set' with a few exceptions, mostly for logging actions. These exceptions are:

- *ClearRecordTypesResponseAction()*
- *KeyValueStoreLookupAction()*
- *DnstapLogAction()*
- *DnstapLogResponseAction()*
- *LimitTTLResponseAction()*
- *LogAction()*
- *NoneAction()*
- *RemoteLogAction()*
- *RemoteLogResponseAction()*
- *SNMPTrapAction()*
- *SNMPTrapResponseAction()*
- *TeeAction()*

The following actions exist.

**AllowAction()**

Let these packets go through.

**AllowResponseAction()**

Let these packets go through.
ClearRecordTypesResponseAction \((\text{types})\)

New in version 1.8.0.

Removes given type(s) records from the response. Beware you can accidentally turn the answer into a NODATA response without a SOA record in the additional section in which case you may want to use \(\text{NegativeAndSOAAction()}\) to generate an answer, see example below. Subsequent rules are processed after this action.

```python
-- removes any HTTPS record in the response
addResponseAction(
    QNameRule('www.example.com.'),
    ClearRecordTypesResponseAction(DNSQType.HTTPS)
)

-- reply directly with NODATA and a SOA record as we know the answer will be empty
addAction(
    AndRule{QNameRule('www.example.com.'), QTypeRule(DNSQType.HTTPS)},
    NegativeAndSOAAction(false, 'example.com.', 3600, 'ns.example.com.', 'postmaster.example.com.', 1, 1800, 900, 604800, 86400)
)
```

Parameters \textit{types} \((\text{int})\) – a single type or a list of types to remove

ContinueAction \((\text{action})\)

New in version 1.4.0.

Execute the specified action and override its return with None, making it possible to continue the processing. Subsequent rules are processed after this action.

Parameters \textit{action} \((\text{int})\) – Any other action

DelayAction \((\text{milliseconds})\)

Delay the response by the specified amount of milliseconds (UDP-only). Note that the sending of the query to the backend, if needed, is not delayed. Only the sending of the response to the client will be delayed. Subsequent rules are processed after this action.

Parameters \textit{milliseconds} \((\text{int})\) – The amount of milliseconds to delay the response

DelayResponseAction \((\text{milliseconds})\)

Delay the response by the specified amount of milliseconds (UDP-only). The only difference between this action and \textit{DelayAction()} is that they can only be applied on, respectively, responses and queries. Subsequent rules are processed after this action.

Parameters \textit{milliseconds} \((\text{int})\) – The amount of milliseconds to delay the response

DisableECSAction()

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use \textit{SetDisableECSAction()} instead.

Disable the sending of ECS to the backend. Subsequent rules are processed after this action.

DisableValidationAction()

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use \textit{SetDisableValidationAction()} instead.

Set the CD bit in the query and let it go through. Subsequent rules are processed after this action.

DnstapLogAction \((\text{identity}, \text{logger}, \text{alterFunction})\)

Send the current query to a remote logger as a \textit{dnstap} message. \textit{alterFunction} is a callback, receiving a \textit{DNSQuestion} and a \textit{DnstapMessage}, that can be used to modify the message. Subsequent rules are processed after this action.

5.5. Actions 29
Parameters

- **identity (string)** – Server identity to store in the dnstap message
- **logger** – The `FrameStreamLogger` or `RemoteLogger` object to write to
- **alterFunction** – A Lua function to alter the message before sending

**DnstapLogResponseAction** (identity, logger[, alterFunction])

Send the current response to a remote logger as a dnstap message. alterFunction is a callback, receiving a `DNSQuestion` and a `DnstapMessage`, that can be used to modify the message. Subsequent rules are processed after this action.

Parameters

- **identity (string)** – Server identity to store in the dnstap message
- **logger** – The `FrameStreamLogger` or `RemoteLogger` object to write to
- **alterFunction** – A Lua function to alter the message before sending

**DropAction**()

Drop the packet.

**DropResponseAction**()

Drop the packet.

**ECSOverrideAction** (override)

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetECSOverrideAction()` instead.

Whether an existing EDNS Client Subnet value should be overridden (true) or not (false). Subsequent rules are processed after this action.

Parameters **override** (bool) – Whether or not to override ECS value

**ECSPrefixLengthAction** (v4, v6)

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetECSPrefixLengthAction()` instead.

Set the ECS prefix length. Subsequent rules are processed after this action.

Parameters

- **v4** (int) – The IPv4 netmask length
- **v6** (int) – The IPv6 netmask length

**ERCodeAction** (rcode[, options])

New in version 1.4.0.

Changed in version 1.5.0: Added the optional parameter options.

Reply immediately by turning the query into a response with the specified EDNS extended rcode. rcode can be specified as an integer or as one of the built-in RCode.

Parameters

- **rcode** (int) – The extended RCODE to respond with.
- **options** (table) – A table with key: value pairs with options.

Options:

- **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.

Chapter 5. Packet Policies
• ra: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.

**HTTPStatusAction** *(status, body, contentType="")*

New in version 1.4.0.

Changed in version 1.5.0: Added the optional parameter `options`.

Return an HTTP response with a status code of `"status"`. For HTTP redirects, `"body"` should be the redirect URL.

**Parameters**

- **status** *(int)* – The HTTP status code to return.
- **body** *(string)* – The body of the HTTP response, or a URL if the status code is a redirect (3xx).
- **contentType** *(string)* – The HTTP Content-Type header to return for a 200 response, ignored otherwise. Default is "application/dns-message".
- **options** *(table)* – A table with key: value pairs with options.

**Options:**

- **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ra**: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.

**KeyValueStoreLookupAction** *(kvs, lookupKey, destinationTag)*

New in version 1.4.0.

Does a lookup into the key value store referenced by ‘kvs’ using the key returned by ‘lookupKey’, and storing the result if any into the tag named ‘destinationTag’. The store can be a CDB *(newCDBKVStore())* or a LMDB database *(newLMDBKVStore())*. The key can be based on the qname *(KeyValueLookupKeyQName() and KeyValueLookupKeySuffix())*, source IP *(KeyValueLookupKeySourceIP())* or the value of an existing tag *(KeyValueLookupKeyTag())*. Subsequent rules are processed after this action. Note that the tag is always created, even if there was no match, but in that case the content is empty.

**Parameters**

- **kvs** *(KeyValueStore)* – The key value store to query
- **lookupKey** *(KeyValueLookupKey)* – The key to use for the lookup
- **destinationTag** *(string)* – The name of the tag to store the result into

**KeyValueStoreRangeLookupAction** *(kvs, lookupKey, destinationTag)*

New in version 1.7.0.

Does a range-based lookup into the key value store referenced by ‘kvs’ using the key returned by ‘lookupKey’, and storing the result if any into the tag named ‘destinationTag’. This assumes that there is a key in network byte order for the last element of the range (for example 2001:0db8:ffff:ffff:ffff:ffff:ffff:ffff for 2001:db8::/32) which contains the first element of the range (2001:0db8:0000:0000:0000:0000:0000:0000) (optionally followed by any data) as value, also in network byte order, and that there is no overlapping ranges in the database. This requires that the underlying store supports ordered keys, which is true for LMDB but not for CDB.

Subsequent rules are processed after this action.

**Parameters**

- **kvs** *(KeyValueStore)* – The key value store to query
• **lookupKey** (*KeyValueLookupKey*) – The key to use for the lookup

• **destinationTag** (*string*) – The name of the tag to store the result into

**LimitTTLResponseAction** (*min*[ , *max*[, *types*]]*)

New in version 1.8.0.

Cap the TTLs of the response to the given boundaries.

**Parameters**

• **min** (*int*) – The minimum allowed value

• **max** (*int*) – The maximum allowed value

• **of int** (*list*) – The record types to cap the TTL for. Default is empty which means all records will be capped.

**LogAction** ([*filename*[, *binary*[ , *append*[ , *buffered*[ , *verboseOnly*[ , *includeTimestamp*]]]]] ])

Changed in version 1.4.0: Added the optional parameters *verboseOnly* and *includeTimestamp*, made *filename* optional.

Changed in version 1.7.0: Added the *reload* method.

Log a line for each query, to the specified file if any, to the console (require verbose) if the empty string is given as filename.

If an empty string is supplied in the file name, the logging is done to stdout, and only in verbose mode by default. This can be changed by setting *verboseOnly* to false.

When logging to a file, the *binary* optional parameter specifies whether we log in binary form (default) or in textual form. Before 1.4.0 the binary log format only included the qname and qtype. Since 1.4.0 it includes an optional timestamp, the query ID, qname, qtype, remote address and port.

The *append* optional parameter specifies whether we open the file for appending or truncate each time (default). The *buffered* optional parameter specifies whether writes to the file are buffered (default) or not.

Since 1.7.0 calling the *reload()* method on the object will cause it to close and re-open the log file, for rotation purposes.

Subsequent rules are processed after this action.

**Parameters**

• **filename** (*string*) – File to log to. Set to an empty string to log to the normal stdout log, this only works when -v is set on the command line.

• **binary** (*bool*) – Do binary logging. Default true

• **append** (*bool*) – Append to the log. Default false

• **buffered** (*bool*) – Use buffered I/O. Default true

• **verboseOnly** (*bool*) – Whether to log only in verbose mode when logging to stdout. Default is true

• **includeTimestamp** (*bool*) – Whether to include a timestamp for every entry. Default is false

**LogResponseAction** ([*filename*, *append*, *buffered*, *verboseOnly*, *includeTimestamp]*)

New in version 1.5.0.

Changed in version 1.7.0: Added the *reload* method.

Log a line for each response, to the specified file if any, to the console (require verbose) if the empty string is given as filename.

If an empty string is supplied in the file name, the logging is done to stdout, and only in verbose mode by default. This can be changed by setting *verboseOnly* to false.
The `append` optional parameter specifies whether we open the file for appending or truncate each time (default). The `buffered` optional parameter specifies whether writes to the file are buffered (default) or not.

Since 1.7.0 calling the `reload()` method on the object will cause it to close and re-open the log file, for rotation purposes. Subsequent rules are processed after this action.

**Parameters**

- `filename (string)` – File to log to. Set to an empty string to log to the normal stdout log, this only works when `-v` is set on the command line.
- `append (bool)` – Append to the log. Default false
- `buffered (bool)` – Use buffered I/O. Default true
- `verboseOnly (bool)` – Whether to log only in verbose mode when logging to stdout. Default is true
- `includeTimestamp (bool)` – Whether to include a timestamp for every entry. Default is false

**LuaAction (function)**

Invoke a Lua function that accepts a `DNSQuestion`.

The function should return a `DNSAction`. If the Lua code fails, ServFail is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**LuaFFIAction (function)**

New in version 1.5.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return a `DNSAction`. If the Lua code fails, ServFail is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**LuaFFIPerThreadAction (function)**

New in version 1.7.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return a `DNSAction`. If the Lua code fails, ServFail is returned.

The function will be invoked in a per-thread Lua state, without access to the global Lua state. All constants (`DNSQType`, `RCode`, ...) are available in that per-thread context, as well as all FFI functions. Objects and their bindings that are not usable in a FFI context (`DNSQuestion`, `DNSDistProtoBufMessage`, `PacketCache`, ...) are not available.

**Parameters**

- `function (string)` – a Lua string returning a Lua function

**LuaFFIPerThreadResponseAction (function)**

New in version 1.7.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return a `DNSResponseAction`. If the Lua code fails, ServFail is returned.

The function will be invoked in a per-thread Lua state, without access to the global Lua state. All constants (`DNSQType`, `RCode`, ...) are available in that per-thread context, as well as all FFI functions. Objects and their bindings that are not usable in a FFI context (`DNSQuestion`, `DNSDistProtoBufMessage`, `PacketCache`, ...) are not available.

**Parameters**

- `function (string)` – a Lua string returning a Lua function
**LuaFFIResponseAction** *(function)*

New in version 1.5.0.

Invoke a Lua FFI function that accepts a pointer to a `dnsdist_ffi_dnsquestion_t` object, whose bindings are defined in `dnsdist-lua-ffi.hh`.

The function should return a `DNSResponseAction`. If the Lua code fails, ServFail is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**LuaResponseAction** *(function)*

Invoke a Lua function that accepts a `DNSResponse`.

The function should return a `DNSResponseAction`. If the Lua code fails, ServFail is returned.

**Parameters**

- `function (string)` – the name of a Lua function

**MacAddrAction** *(option)*

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetMacAddrAction()` instead.

Add the source MAC address to the query as EDNS0 option `option`. This action is currently only supported on Linux. Subsequent rules are processed after this action.

**Parameters**

- `option (int)` – The EDNS0 option number

**NegativeAndSOAAction** *(nxd, zone, ttl, mname, rname, serial, refresh, retry, expire, minimum[, options]*)

New in version 1.6.0.

Changed in version 1.8.0: Added the `soaInAuthoritySection` option.

Turn a question into a response, either a NXDOMAIN or a NODATA one based on “nxd”, setting the QR bit to 1 and adding a SOA record in the additional section. Note that this function was called `SetNegativeAndSOAAction()` before 1.6.0.

**Parameters**

- `nxd (bool)` – Whether the answer is a NXDOMAIN (true) or a NODATA (false)
- `zone (string)` – The owner name for the SOA record
- `ttl (int)` – The TTL of the SOA record
- `mname (string)` – The mname of the SOA record
- `rname (string)` – The rname of the SOA record
- `serial (int)` – The value of the serial field in the SOA record
- `refresh (int)` – The value of the refresh field in the SOA record
- `retry (int)` – The value of the retry field in the SOA record
- `expire (int)` – The value of the expire field in the SOA record
- `minimum (int)` – The value of the minimum field in the SOA record
- `options (table)` – A table with key: value pairs with options

**Options:**

- `aa`: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- `ad`: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- `ra`: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.
• `soaInAuthoritySection`: bool - Place the SOA record in the authority section for a complete NXDOMAIN/NODATA response that works as a cacheable negative response, rather than the RPZ-style response with a purely informational SOA in the additional section. Default is false (SOA in additional section).

**NoneAction()**

Does nothing. Subsequent rules are processed after this action.

**NoRecurseAction()**

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetNoRecurseAction()` instead.

Strip RD bit from the question, let it go through. Subsequent rules are processed after this action.

**PoolAction(poolname[, stop])**

Changed in version 1.8.0: Added the `stop` optional parameter.

Send the packet into the specified pool. If `stop` is set to false, subsequent rules will be processed after this action.

**Parameters**

- `poolname` (string) – The name of the pool
- `stop` (bool) – Whether to stop processing rules after this action. Default is true, meaning the remaining rules will not be processed.

**QPSAction(maxqps)**

Drop a packet if it does exceed the `maxqps` queries per second limits. Letting the subsequent rules apply otherwise.

**Parameters**

- `maxqps` (int) – The QPS limit

**QPSPoolAction(maxqps, poolname[, stop])**

Changed in version 1.8.0: Added the `stop` optional parameter.

Send the packet into the specified pool only if it does not exceed the `maxqps` queries per second limits. If `stop` is set to false, subsequent rules will be processed after this action. Letting the subsequent rules apply otherwise.

**Parameters**

- `maxqps` (int) – The QPS limit for that pool
- `poolname` (string) – The name of the pool
- `stop` (bool) – Whether to stop processing rules after this action. Default is true, meaning the remaining rules will not be processed.

**RCodeAction(rcode[, options])**

Changed in version 1.5.0: Added the optional parameter `options`.

Reply immediately by turning the query into a response with the specified `rcode`. `rcode` can be specified as an integer or as one of the built-in `RCode`.

**Parameters**

- `rcode` (int) – The RCODE to respond with.
- `options` (table) – A table with key: value pairs with options.

**Options:**

- `aa`: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- `ad`: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
• ra: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.

**RemoteLogAction** *(remoteLogger*, *alterFunction*, *options*, *metas]*)

Changed in version 1.4.0: ipEncryptKey optional key added to the options table.

Changed in version 1.8.0: metas optional parameter added. exportTags optional key added to the options table.

Send the content of this query to a remote logger via Protocol Buffer. alterFunction is a callback, receiving a DNSQuestion and a DNSDistProtoBufMessage, that can be used to modify the Protocol Buffer content, for example for anonymization purposes. Since 1.8.0 it is possible to add configurable metadata fields to the Protocol Buffer message via the metas parameter, which takes a list of name``=``key pairs. For each entry in the list, a new value named name will be added to the message with the value corresponding to the key. Available keys are:

• **doh-header:<HEADER>**: the content of the corresponding <HEADER> HTTP header for DoH queries, empty otherwise
• **doh-host**: the Host header for DoH queries, empty otherwise
• **doh-path**: the HTTP path for DoH queries, empty otherwise
• **doh-query-string**: the HTTP query string for DoH queries, empty otherwise
• **doh-scheme**: the HTTP scheme for DoH queries, empty otherwise
• **pool**: the currently selected pool of servers
• **proxy-protocol-value:<TYPE>**: the content of the proxy protocol value of type <TYPE>, if any
• **proxy-protocol-values**: the content of all proxy protocol values as a “<type1>:<value1>”, ..., “<typeN>:<valueN>” strings
• **b64-content**: the base64-encoded DNS payload of the current query
• **sni**: the Server Name Indication value for queries received over DoT or DoH. Empty otherwise.
• **tag:<TAG>**: the content of the corresponding <TAG> if any
• **tags**: the list of all tags, and their values, as a “<key1>:<value1>”, ..., “<keyN>:<valueN>” strings. Note that a tag with an empty value will be exported as “<key>”, not “<key>!".

Subsequent rules are processed after this action.

**Parameters**

• **remoteLogger**(string) – The remoteLogger object to write to
• **alterFunction**(string) – Name of a function to modify the contents of the logs before sending
• **options**(table) – A table with key: value pairs.
• **metas**(table) – A list of name``=``key pairs, for meta-data to be added to Protocol Buffer message.

**Options:**

• **serverID="": str** - Set the Server Identity field.
• **ipEncryptKey="": str** - A key, that can be generated via the makeIPCipherKey() function, to encrypt the IP address of the requestor for anonymization purposes. The encryption is done using ipcrypt for IPv4 and a 128-bit AES ECB operation for IPv6.
• **exportTags="": str** - The comma-separated list of keys of internal tags to export into the tags Protocol Buffer field, as “key:value” strings. Note that a tag with an empty value will be exported as “<key>”, not “<key>!". An empty string means that no internal tag will be exported. The special value * means that all tags will be exported.
RemoteLogResponseAction (remoteLogger, alterFunction, includeCNAME, options, metas)

Changed in version 1.4.0: ipEncryptKey optional key added to the options table.

Changed in version 1.8.0: metas optional parameter added. exportTags optional key added to the options table.

Changed in version 1.9.0: exportExtendedErrorsToMeta optional key added to the options table.

Send the content of this response to a remote logger via Protocol Buffer. alterFunction is the same callback that receiving a DNSQuestion and a DNSDistProtoBufMessage, that can be used to modify the Protocol Buffer content, for example for anonymization purposes. includeCNAME indicates whether CNAME records inside the response should be parsed and exported. The default is to only exports A and AAAA records. Since 1.8.0 it is possible to add configurable meta-data fields to the Protocol Buffer message via the metas parameter, which takes a list of name=""=""key" pairs. See RemoteLogAction() for the list of available keys. Subsequent rules are processed after this action.

Parameters

- **remoteLogger** (string) – The remoteLogger object to write to
- **alterFunction** (string) – Name of a function to modify the contents of the logs before sending
- **includeCNAME** (bool) – Whether or not to parse and export CNAMEs. Default false
- **options** (table) – A table with key: value pairs.
- **metas** (table) – A list of name=""=""key" pairs, for meta-data to be added to Protocol Buffer message.

Options:

- **serverID=""**: str - Set the Server Identity field.
- **ipEncryptKey=""**: str - A key, that can be generated via the makeIPCipherKey() function, to encrypt the IP address of the requestor for anonymization purposes. The encryption is done using ipcrypt for IPv4 and a 128-bit AES ECB operation for IPv6.
- **exportTags=""**: str - The comma-separated list of keys of internal tags to export into the tags Protocol Buffer field, as “key:value” strings. Note that a tag with an empty value will be exported as “<key>”, not “<key>:”. An empty string means that no internal tag will be exported. The special value * means that all tags will be exported.
- **exportExtendedErrorsToMeta=""**: str - Export Extended DNS Errors present in the DNS response, if any, into the meta Protocol Buffer field using the specified key. The EDE info code will be exported as an integer value, and the EDE extra text, if present, as a string value.

SetAdditionalProxyProtocolValueAction (type, value)

New in version 1.6.0.

Add a Proxy-Protocol Type-Length value to be sent to the server along with this query. It does not replace any existing value with the same type but adds a new value. Be careful that Proxy Protocol values are sent once at the beginning of the TCP connection for TCP and DoT queries. That means that values received on an incoming TCP connection will be inherited by subsequent queries received over the same incoming TCP connection, if any, but values set to a query will not be inherited by subsequent queries. Subsequent rules are processed after this action.

Parameters

- **type** (int) – The type of the value to send, ranging from 0 to 255 (both included)
- **value** (str) – The binary-safe value

SetDisableECSAction()

New in version 1.6.0.

Disable the sending of ECS to the backend. Subsequent rules are processed after this action. Note that this function was called DisableECSAction() before 1.6.0.
SetDisableValidationAction()  
New in version 1.6.0.  
Set the CD bit in the query and let it go through. Subsequent rules are processed after this action. Note that this function was called DisableValidationAction() before 1.6.0.

SetECSAction((v4[], v6])  
Set the ECS prefix and prefix length sent to backends to an arbitrary value. If both IPv4 and IPv6 masks are supplied the IPv4 one will be used for IPv4 clients and the IPv6 one for IPv6 clients. Otherwise the first mask is used for both, and can actually be an IPv6 mask. Subsequent rules are processed after this action.

Parameters  
• v4 (string) – The IPv4 netmask, for example “192.0.2.1/32”  
• v6 (string) – The IPv6 netmask, if any

SetECSOverrideAction(override)  
New in version 1.6.0.  
Whether an existing EDNS Client Subnet value should be overridden (true) or not (false). Subsequent rules are processed after this action. Note that this function was called ECSOverrideAction() before 1.6.0.

Parameters  
override (bool) – Whether or not to override ECS value

SetECSPrefixLengthAction(v4, v6)  
New in version 1.6.0.  
Set the ECS prefix length. Subsequent rules are processed after this action. Note that this function was called ECSPrefixLengthAction() before 1.6.0.

Parameters  
• v4 (int) – The IPv4 netmask length  
• v6 (int) – The IPv6 netmask length

SetEDNSOptionAction(option)  
New in version 1.7.0.  
Add arbitrary EDNS option and data to the query. Any existing EDNS content with the same option code will be overwritten. Subsequent rules are processed after this action.

Parameters  
• option (int) – The EDNS option number  
• data (string) – The EDNS0 option raw content

SetExtendedDNSErrorCodeAction(infoCode[], extraText])  
New in version 1.9.0.  
Set an Extended DNS Error status that will be added to the response corresponding to the current query. Subsequent rules are processed after this action.

Parameters  
• infoCode (int) – The EDNS Extended DNS Error code  
• extraText (string) – The optional EDNS Extended DNS Error extra text

SetExtendedDNSErrorCodeResponseAction(infoCode[], extraText])  
New in version 1.9.0.  
Set an Extended DNS Error status that will be added to this response. Subsequent rules are processed after this action.

Parameters  
• infoCode (int) – The EDNS Extended DNS Error code  
• extraText (string) – The optional EDNS Extended DNS Error extra text
SetMacAddrAction (option)
New in version 1.6.0.

Add the source MAC address to the query as EDNS0 option `option`. This action is currently only supported on Linux. Subsequent rules are processed after this action. Note that this function was called `MacAddrAction()` before 1.6.0.

**Parameters**
- `option (int)` – The EDNS0 option number

SetMaxReturnedTTLAction (max)
New in version 1.8.0.

Cap the TTLs of the response to the given maximum, but only after inserting the response into the packet cache with the initial TTL values.

**Parameters**
- `max (int)` – The maximum allowed value

SetMaxReturnedTTLResponseAction (max)
New in version 1.8.0.

Cap the TTLs of the response to the given maximum, but only after inserting the response into the packet cache with the initial TTL values.

**Parameters**
- `max (int)` – The maximum allowed value

SetMaxTTLResponseAction (max)
New in version 1.8.0.

Cap the TTLs of the response to the given maximum.

**Parameters**
- `max (int)` – The maximum allowed value

SetMinTTLResponseAction (min)
New in version 1.8.0.

Cap the TTLs of the response to the given minimum.

**Parameters**
- `min (int)` – The minimum allowed value

SetNoRecurseAction ()
New in version 1.6.0.

Strip RD bit from the question, let it go through. Subsequent rules are processed after this action. Note that this function was called `NoRecurseAction()` before 1.6.0.

SetNegativeAndSOAAction (nxd, zone, ttl, mname, rname, serial, refresh, retry, expire, minimum[, options])
New in version 1.5.0.

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `NegativeAndSOAAction()` instead.

Turn a question into a response, either a NXDOMAIN or a NODATA one based on ’nxd’, setting the QR bit to 1 and adding a SOA record in the additional section.

**Parameters**
- `nxd (bool)` – Whether the answer is a NXDOMAIN (true) or a NODATA (false)
- `zone (string)` – The owner name for the SOA record
- `ttl (int)` – The TTL of the SOA record
- `mname (string)` – The mname of the SOA record
- `rname (string)` – The name of the SOA record
- `serial (int)` – The value of the serial field in the SOA record
- `refresh (int)` – The value of the refresh field in the SOA record
• **retry**(int) – The value of the retry field in the SOA record
• **expire**(int) – The value of the expire field in the SOA record
• **minimum**(int) – The value of the minimum field in the SOA record
• **options**(table) – A table with key: value pairs with options

Options:
• **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
• **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
• **ra**: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.

**SetProxyProtocolValuesAction**(values)
New in version 1.5.0.
Set the Proxy-Protocol Type-Length values to be sent to the server along with this query to values. Subsequent rules are processed after this action.

Parameters values(table) – A table of types and values to send, for example: `{[0] = "foo", [42] = "bar"}`

**SetReducedTTLResponseAction**(percentage)
New in version 1.8.0.
Reduce the TTL of records in a response to a percentage of the original TTL. For example, passing 50 means that the original TTL will be cut in half. Subsequent rules are processed after this action.

Parameters percentage(int) – The percentage to use

**SetSkipCacheAction**( )
New in version 1.6.0.
Don’t lookup the cache for this query, don’t store the answer. Subsequent rules are processed after this action. Note that this function was called **SkipCacheAction**( ) before 1.6.0.

**SetSkipCacheResponseAction**( )
New in version 1.6.0.
Don’t store this answer into the cache. Subsequent rules are processed after this action.

**SetTagAction**(name, value)
New in version 1.6.0.
Changed in version 1.7.0: Prior to 1.7.0 **SetTagAction**( ) would not overwrite an existing tag value if already set.

Associate a tag named name with a value of value to this query, that will be passed on to the response. This function will overwrite any existing tag value. Subsequent rules are processed after this action. Note that this function was called **TagAction**( ) before 1.6.0.

Parameters
• name(string) – The name of the tag to set
• value(string) – The value of the tag

**SetTagResponseAction**(name, value)
New in version 1.6.0.
Changed in version 1.7.0: Prior to 1.7.0 **SetTagResponseAction**( ) would not overwrite an existing tag value if already set.
Associate a tag named `name` with a value of `value` to this response. This function will overwrite any existing tag value. Subsequent rules are processed after this action. Note that this function was called `TagResponseAction()` before 1.6.0.

**Parameters**
- `name (string)` – The name of the tag to set
- `value (string)` – The value of the tag

**SetTempFailureCacheTTLAction**( `ttl` )

New in version 1.6.0.

Set the cache TTL to use for ServFail and Refused replies. TTL is not applied for successful replies. Subsequent rules are processed after this action. Note that this function was called `TempFailureCacheTTLAction()` before 1.6.0.

**Parameters**
- `ttl (int)` – Cache TTL for temporary failure replies

**SkipCacheAction()**

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetSkipAction()` instead.

Don’t lookup the cache for this query, don’t store the answer. Subsequent rules are processed after this action.

**SNMPTrapAction**( `message` )

Send an SNMP trap, adding the optional `message` string as the query description. Subsequent rules are processed after this action.

**Parameters**
- `message (string)` – The message to include

**SNMPTrapResponseAction**( `message` )

Send an SNMP trap, adding the optional `message` string as the query description. Subsequent rules are processed after this action.

**Parameters**
- `message (string)` – The message to include

**SpoofAction**( `ip`, `options` )

Changed in version 1.5.0: Added the optional parameter `options`.

Changed in version 1.6.0: Up to 1.6.0, the syntax for this function was `SpoofAction(ips[, ip[, options]])`.

Forge a response with the specified IPv4 (for an A query) or IPv6 (for an AAAA) addresses. If you specify multiple addresses, all that match the query type (A, AAAA or ANY) will get spoofed in.

**Parameters**
- `ip (string)` – An IPv4 and/or IPv6 address to spoof
- `ips ((string))` – A table of IPv4 and/or IPv6 addresses to spoof
- `options (table)` – A table with key: value pairs with options.

**Options:**
- `aa`: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- `ad`: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- `ra`: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.
- `ttl`: int - The TTL of the record.
SpoofCNAMEAction(cname, options)

Changed in version 1.5.0: Added the optional parameter options.

Forge a response with the specified CNAME value.

Parameters

- **cname**(string) – The name to respond with
- **options**(table) – A table with key: value pairs with options.

Options:

- **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ra**: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.
- **ttl**: int - The TTL of the record.

SpoofRawAction(rawAnswer, options)

New in version 1.5.0.

Changed in version 1.6.0: Up to 1.6.0, it was only possible to spoof one answer.

Changed in version 1.9.0: Added the optional parameter typeForAny.

Forge a response with the specified raw bytes as record data.

```lua
-- select queries for the 'raw.powerdns.com.' name and TXT type, and answer with both a "aaa" "bbbb" and "ccc" TXT record:
addAction(AndRule({QNameRule('raw.powerdns.com.'), QTypeRule(DNSQType.TXT)}),
SpoofRawAction({"\003aaa\004bbbb", "\003ccc"}))
-- select queries for the 'raw-srv.powerdns.com.' name and SRV type, and answer with a '0 0 65535 srv.powerdns.com.' SRV record, setting the AA bit to 1 and the TTL to 3600s
addAction(AndRule({QNameRule('raw-srv.powerdns.com.'), QTypeRule(DNSQType.SRV)}),
SpoofRawAction("\000\000\000\000\255\255\003srv\008powerdns\003com\000",
{ aa=true, ttl=3600 }))
-- select reverse queries for '127.0.0.1' and answer with 'localhost'
addAction(AndRule({QNameRule('1.0.0.127.in-addr.arpa.'), QTypeRule(DNSQType.PTR)}),
SpoofRawAction("\009localhost\000"))
-- rfc8482: Providing Minimal-Sized Responses to DNS Queries That Have QTYPE=ANY via HINFO of value "rfc8482"
addAction(QTypeRule(DNSQType.ANY),
SpoofRawAction("\007rfc\056\052\056\050\000",
{ typeForAny=DNSQType.HINFO }))
```

DNSName:toDNSString() is convenient for converting names to wire format for passing to SpoofRawAction.

sdig dumpluaraw and pdnsutil raw-lua-from-content from PowerDNS can generate raw answers for you:

```bash
$ pdnsutil raw-lua-from-content SRV '0 0 65535 srv.powerdns.com.' "\000\000\000\000\255\255\003srv\008powerdns\003com\000"
$ sdig 127.0.0.1 53 open-xchange.com MX recurse dumpluaraw
Reply to question for qname='open-xchange.com.', qtype=MX
Rcode: 0 (No Error), RD: 1, QR: 1, TC: 0, AA: 0, opcode: 0
0 open-xchange.com. IN MX "\000\004mx\049\049\012open\045xchange\003com\000"
0 open-xchange.com. IN MX "\000\010\003mx\049\012open\045xchange\003com\000"
0 open-xchange.com. IN MX "\000\020\003mx\050\012open\045xchange\003com\000"
```

42 Chapter 5. Packet Policies
Parameters

- **rawAnswer** *(string)* – The raw record data
- **rawAnswers** *(dict)* – A table of raw record data to spoof
- **options** *(table)* – A table with key: value pairs with options.

Options:

- **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ra**: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.
- **ttl**: int - The TTL of the record.
- **typeForAny**: int - The record type to use when responding to queries of type ANY, as using ANY for the type of the response record would not make sense.

**SpoofSVCAction** *(svcParams[, options ])*

New in version 1.7.0.

Forge a response with the specified SVC record data. If the list contains more than one class:**SVCRecordParameters** (generated via **newSVCRecordParameters**()) object, they are all returned, and should have different priorities. The hints provided in the SVC parameters, if any, will also be added as A/AAAA records in the additional section, using the target name present in the parameters as owner name if it’s not empty (root) and the qname instead.

: :param list of class:**SVCRecordParameters** svcParams: The record data to return : :param table options: A table with key: value pairs with options.

Options:

- **aa**: bool - Set the AA bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ad**: bool - Set the AD bit to this value (true means the bit is set, false means it’s cleared). Default is to clear it.
- **ra**: bool - Set the RA bit to this value (true means the bit is set, false means it’s cleared). Default is to copy the value of the RD bit from the incoming query.
- **ttl**: int - The TTL of the record.

**SpoofPacketAction** *(rawPacket, len)*

New in version 1.8.0.

Spoof a raw self-generated answer

**Parameters**

- **rawPacket** *(string)* – The raw wire-ready DNS answer
- **len** *(int)* – The length of the packet

**TagAction** *(name, value)*

Deprecated since version 1.6.0: This function has been deprecated in 1.6.0 and removed in 1.7.0, please use **SetTagAction**() instead.

Associate a tag named **name** with a value of **value** to this query, that will be passed on to the response. Subsequent rules are processed after this action.

**Parameters**

- **name** *(string)* – The name of the tag to set
TagResponseAction \( (name, value) \)

Depreciated since version 1.6.0: This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetTagResponseAction()` instead.

Associate a tag named \( name \) with a value of \( value \) to this response. Subsequent rules are processed after this action.

Parameters

- \( name (string) \) – The name of the tag to set
- \( value (string) \) – The value of the tag

TCAction()

Changed in version 1.7.0: This action is now only performed over UDP transports.

Create answer to query with the TC bit set, and the RA bit set to the value of RD in the query, to force the client to TCP. Before 1.7.0 this action was performed even when the query had been received over TCP, which required the use of `TCPRule()` to prevent the TC bit from being set over TCP transports.

TCResponseAction()

New in version 1.9.0.

Truncate an existing answer, to force the client to TCP. Only applied to answers that will be sent to the client over TCP. In addition to the TC bit being set, all records are removed from the answer, authority and additional sections.

TeeAction \( \{remote[, addECS[, local[, addProxyProtocol ]]]\} \)

Changed in version 1.8.0: Added the optional parameter `local`.

Changed in version 1.9.0: Added the optional parameter `addProxyProtocol`.

Send copy of query to `remote`, keep stats on responses. If `addECS` is set to true, EDNS Client Subnet information will be added to the query. If `addProxyProtocol` is set to true, a Proxy Protocol v2 payload will be prepended in front of the query. The payload will contain the protocol the initial query was received over (UDP or TCP), as well as the initial source and destination addresses and ports. If `local` has provided a value like “192.0.2.53”, `dnsdist` will try binding that address as local address when sending the queries. Subsequent rules are processed after this action.

Parameters

- \( remote (string) \) – An IP:PORT combination to send the copied queries to
- \( addECS (bool) \) – Whether to add ECS information. Default false.
- \( local (str) \) – The local address to use to send queries. The default is to let the kernel pick one.
- \( addProxyProtocol (bool) \) – Whether to prepend a proxy protocol v2 payload in front of the query. Default to false.

TempFailureCacheTTLAction \( (nl) \)

Deprecated since version 1.6.0.

This function has been deprecated in 1.6.0 and removed in 1.7.0, please use `SetTempFailureCacheTTLAction()` instead.

Set the cache TTL to use for ServFail and Refused replies. TTL is not applied for successful replies. Subsequent rules are processed after this action.

Parameters \( ttl (int) \) – Cache TTL for temporary failure replies
5.6 Objects

class DNSDistRuleAction
   New in version 1.9.0.
   Represents a rule composed of a DNSRule selector, to select the queries this applies to, and a DNSAction action to apply when the selector matches.

   :getAction()
   Return the DNSAction action of this rule.

   :getSelector()
   Return the DNSRule selector of this rule.

class DNSDistResponseRuleAction
   New in version 1.9.0.
   Represents a rule composed of a DNSRule selector, to select the responses this applies to, and a DNSResponseAction action to apply when the selector matches.

   :getAction()
   Return the DNSResponseAction action of this rule.

   :getSelector()
   Return the DNSRule selector of this rule.

class DNSRule
   New in version 1.9.0.

   :getMatches() → int
   Return the number of times this selector matched a query or a response. Note that if the same selector is reused for different DNSDistRuleAction objects, the counter will be common to all these objects.
**STATISTICS**

`dnsdist` keeps statistics on the queries it receives and send out. They can be accessed in different ways:

- via the console (see *Working with the dnsdist Console*), using `dumpStats()` for the general ones, `showServers()` for the ones related to the backends, `showBinds()` for the frontends, `getPool("pool name").getCache().printStats()` for the ones related to a specific cache and so on
- via the internal webserver (see *Built-in webserver*) which includes a Prometheus endpoint
- via Carbon / Graphite / Metronome export (see *Exporting statistics via Carbon*)
- via SNMP (see *SNMP support*)

To make sense of the statistics, the following relation should hold:

\[
\text{queries} - \text{noncompliant-queries} = \text{responses} - \text{noncompliant-responses} + \text{downstream-timeouts} + \text{no-policy} + \text{rule-drop}
\]

Before 1.8.0, cache hits and self-answered responses were not accounted in the responses counters, so the relation was:

\[
\text{responses} - \text{noncompliant-responses} + \text{cache-hits} + \text{downstream-timeouts} + \text{self-answered} + \text{no-policy} + \text{rule-drop}
\]

Note that packets dropped by eBPF (see *eBPF Socket Filtering*) are accounted for in the eBPF statistics, and do not show up in the metrics described on this page.

Note that counters that come from `/proc/net/` are operating system specific counters. They do not reset on service restart and they are not only related to `dnsdist`. For more information on these counters, refer to Linux networking counter documentation and the RFC1213.

### 6.1 acl-drops

The number of packets (or TCP messages) dropped because of the *ACL*. If a packet or message is dropped, it is not counted in the `queries` statistic.

### 6.2 cache-hits

Number of times a response was sent using data found in the `packet cache`.

### 6.3 cache-misses

Number of times an answer was not found in the `packet cache`. Only counted if a packet cache was setup for the selected pool.
6.4 cpu-iowait

New in version 1.5.0.
Time spent waiting for I/O to complete by the whole system, in units of USER_HZ.

6.5 cpu-steal

New in version 1.5.0.
Stolen time, which is the time spent by the whole system in other operating systems when running in a virtualized environment, in units of USER_HZ.

6.6 cpu-sys-msec

Milliseconds spent by dnsdist in the “system” state.

6.7 cpu-user-msec

Milliseconds spent by dnsdist in the “user” state.

6.8 doh-query-pipe-full

Number of queries dropped because the internal DoH pipe was full.

6.9 doh-response-pipe-full

Number of responses dropped because the internal DoH pipe was full.

6.10 doq-response-pipe-full

Number of responses dropped because the internal DoQ pipe was full.

6.11 downstream-send-errors

Number of errors when sending a query to a backend.

6.12 downstream-timeouts

Number of queries not answer in time by a backend.

6.13 dyn-block-nmg-size

Number of dynamic blocks entries.
6.14 dyn-blocked

Number of queries dropped because of a dynamic block.

6.15 empty-queries

Number of empty queries received from clients. Every empty-query is also counted as a query.

6.16 fd-usage

Number of currently used file descriptors.

6.17 frontend-noerror

Number of NoError answers sent to clients.

6.18 frontend-nxdomain

Number of NXDomain answers sent to clients.

6.19 frontend-servfail

Number of ServFail answers sent to clients.

6.20 latency-avg100

Average response latency in microseconds of the last 100 packets received over UDP.

6.21 latency-avg1000

Average response latency in microseconds of the last 1000 packets received over UDP.

6.22 latency-avg10000

Average response latency in microseconds of the last 10000 packets received over UDP.

6.23 latency-avg1000000

Average response latency in microseconds of the last 1000000 packets received over UDP.
6.24 latency-bucket

Histogram of response time latencies for queries received over UDP.

6.25 latency-count

Number of queries contributing to response time histogram and latency sum.

6.26 latency-doh-avg100

Average response latency, in microseconds, of the last 100 packets received over DoH.

6.27 latency-doh-avg1000

Average response latency, in microseconds, of the last 1000 packets received over DoH.

6.28 latency-doh-avg10000

Average response latency, in microseconds, of the last 10000 packets received over DoH.

6.29 latency-doh-avg1000000

Average response latency, in microseconds, of the last 1000000 packets received over DoH.

6.30 latency-doq-avg100

Average response latency, in microseconds, of the last 100 packets received over DoQ.

6.31 latency-doq-avg1000

Average response latency, in microseconds, of the last 1000 packets received over DoQ.

6.32 latency-doq-avg10000

Average response latency, in microseconds, of the last 10000 packets received over DoQ.

6.33 latency-doq-avg1000000

Average response latency, in microseconds, of the last 1000000 packets received over DoQ.
6.34 latency-dot-avg100

Average response latency, in microseconds, of the last 100 packets received over DoT.

6.35 latency-dot-avg1000

Average response latency, in microseconds, of the last 1000 packets received over DoT.

6.36 latency-dot-avg10000

Average response latency, in microseconds, of the last 10000 packets received over DoT.

6.37 latency-dot-avg1000000

Average response latency, in microseconds, of the last 1000000 packets received over DoT.

6.38 latency-slow

Number of queries received over UDP answered in more than 1 second.

6.39 latency-sum

Total response time of all queries received over UDP combined in milliseconds since the start of dnsdist. Can be used to calculate the average response time over all queries received over UDP.

6.40 latency-tcp-avg100

Average response latency, in microseconds, of the last 100 packets received over TCP.

6.41 latency-tcp-avg1000

Average response latency, in microseconds, of the last 1000 packets received over TCP.

6.42 latency-tcp-avg10000

Average response latency, in microseconds, of the last 10000 packets received over TCP.

6.43 latency-tcp-avg1000000

Average response latency, in microseconds, of the last 1000000 packets received over TCP.
6.44 latency0-1
Number of queries received over UDP answered in less than 1 ms.

6.45 latency1-10
Number of queries received over UDP answered in 1-10 ms.

6.46 latency10-50
Number of queries received over UDP answered in 10-50 ms.

6.47 latency50-100
Number of queries received over UDP answered in 50-100 ms.

6.48 latency100-1000
Number of queries received over UDP answered in 100-1000 ms.

6.49 no-policy
Number of queries dropped because no server was available.

6.50 noncompliant-queries
Number of queries dropped as non-compliant.

6.51 noncompliant-responses
Number of answers from a backend dropped as non-compliant.

6.52 outgoing-doh-query-pipe-full
Number of outgoing DoH queries dropped because the internal pipe used to distribute queries was full.

6.53 proxy-protocol-invalid
New in version 1.6.0.
Number of queries dropped because of an invalid Proxy Protocol header.
6.54 queries

Number of received queries.

6.55 rdqueries

Number of received queries with the recursion desired bit set.

6.56 real-memory-usage

Current memory usage.

6.57 responses

Number of response sent to clients.
Before 1.8.0, it was the number of responses received from backends, not accounting for cache hits or self-answered responses.

6.58 rule-drop

Number of queries dropped because of a rule.

6.59 rule-nxdomain

Number of NXDomain answers returned because of a rule.

6.60 rule-refused

Number of Refused answers returned because of a rule.

6.61 rule-servfail

Number of ServFail answers returned because of a rule.

6.62 rule-truncated

New in version 1.6.0.
Number of truncated answers returned because of a rule.
6.63 security-status

The security status of `dnsdist`. This is regularly polled.

- 0 = Unknown status or unreleased version
- 1 = OK
- 2 = Upgrade recommended
- 3 = Upgrade required (most likely because there is a known security issue)

6.64 self-answered

Number of self-answered responses.

6.65 servfail-responses

Number of servfail answers received from backends.

6.66 tcp-cross-protocol-query-pipe-full

Number of TCP cross-protocol queries dropped because the internal pipe used to distribute queries was full.

6.67 tcp-cross-protocol-response-pipe-full

Number of TCP cross-protocol responses dropped because the internal pipe used to distribute queries was full.

6.68 tcp-listen-overflows

New in version 1.6.0.

From `/proc/net/netstat ListenOverflows`.

6.69 tcp-query-pipe-full

Number of TCP queries dropped because the internal pipe used to distribute queries was full.

6.70 trunc-failures

Number of errors encountered while truncating an answer.

6.71 udp-in-csum-errors

New in version 1.7.0.

From `/proc/net/snmp InErrors`.
6.72 udp-in-errors

New in version 1.5.0.
From /proc/net/snmp InErrors.

6.73 udp-noport-errors

New in version 1.5.0.
From /proc/net/snmp NoPorts.

6.74 udp-recvbuf-errors

New in version 1.5.0.
From /proc/net/snmp RcvbufErrors.

6.75 udp-sndbuf-errors

New in version 1.5.0.
From /proc/net/snmp SndbufErrors.

6.76 udp6-in-csum-errors

New in version 1.7.0.
From /proc/net/snmp6 InErrors.

6.77 udp6-in-errors

New in version 1.7.0.
From /proc/net/snmp6 InErrors.

6.78 udp6-noport-errors

New in version 1.7.0.
From /proc/net/snmp6 NoPorts.

6.79 udp6-recvbuf-errors

New in version 1.7.0.
From /proc/net/snmp6 RcvbufErrors.
6.80 udp6-sndbuf-errors

New in version 1.7.0.
From /proc/net/snmp6SndbufErrors.

6.81 uptime

Uptime of the dnsdist process, in seconds.
CHAPTER
SEVEN

CACHING RESPONSES

dnsdist implements a simple but effective packet cache, not enabled by default. It is enabled per-pool, but the same cache can be shared between several pools. The first step is to define a cache with `newPacketCache()`, then to assign that cache to the chosen pool, the default one being represented by the empty string:

```lua
pc = newPacketCache(10000, {maxTTL=86400, minTTL=0, temporaryFailureTTL=60, 
   →staleTTL=60, dontAge=false})
getPool(""):setCache(pc)
```

- The first parameter (10000) is the maximum number of entries stored in the cache, and is the only one required. All the other parameters are optional and in seconds, except the last one which is a boolean.
- The second one (86400) is the maximum lifetime of an entry in the cache.
- The third one (0) is the minimum TTL an entry should have to be considered for insertion in the cache.
- The fourth one (60) is the TTL used for a Server Failure or a Refused response.
- The fifth one (60) is the TTL that will be used when a stale cache entry is returned.
- The sixth one is a boolean that when set to true, avoids reducing the TTL of cached entries.

For performance reasons the cache will pre-allocate buckets based on the maximum number of entries, so be careful to set the first parameter to a reasonable value. Something along the lines of a dozen bytes per pre-allocated entry can be expected on 64-bit. That does not mean that the memory is completely allocated up-front, the final memory usage depending mostly on the size of cached responses and therefore varying during the cache’s lifetime. Assuming an average response size of 512 bytes, a cache size of 10000000 entries on a 64-bit host with 8GB of dedicated RAM would be a safe choice.

The `setStaleCacheEntriesTTL()` directive can be used to allow dnsdist to use expired entries from the cache when no backend is available. Only entries that have expired for less than n seconds will be used, and the returned TTL can be set when creating a new cache with `newPacketCache()`.

A reference to the cache affected to a specific pool can be retrieved with:

```lua
getPool("poolname"):getCache()
```

And removed with:

```lua
getPool("poolname"):unsetCache()
```

Cache usage stats (hits, misses, deferred inserts and lookups, collisions) can be displayed by using the `PacketCache:printStats()` method:

```lua
getPool("poolname"):getCache():printStats()
```

The same values can also be returned as a Lua table, which is easier to work with from a script, using the `PacketCache:getStats()` method.

Expired cached entries can be removed from a cache using the `PacketCache:purgeExpired()` method, which will remove expired entries from the cache until at most n entries remain in the cache. For example, to remove all expired entries:

```lua
getPool("poolname"):getCache():purgeExpired()
```
Specific entries can also be removed using the `PacketCache:expungeByName()` method:

```
getPool("poolname").getCache().expungeByName(newDNSName("powerdns.com"), DNSQType.A)
```

Changed in version 1.4.0: Before 1.4.0, the QTypes were in the `dnsdist` namespace. Use `dnsdist.A` in these versions.

Finally, the `PacketCache:expunge()` method will remove all entries until at most n entries remain in the cache:

```
getPool("poolname").getCache().expunge(0)
```
8.1 Setting up a carbon export

To emit metrics to Graphite, or any other software supporting the Carbon protocol, use:

```
carbonServer('ip-address-of-carbon-server', 'ourname', 30, 'dnsdist', 'main')
```

Where `ourname` can be used to override your hostname, and 30 is the reporting interval in seconds. `dnsdist` and `main` are used as namespace and instance variables. For querycount statistics these two variables are currently ignored. The last four arguments can be omitted. The latest version of PowerDNS Metronome comes with attractive graphs for `dnsdist` by default.

8.2 Query counters

In addition to other metrics, it is possible to send per-records statistics of the amount of queries by using `setQueryCount()` with query counting enabled, `dnsdist` will increase a counter for every unique record or the behaviour you define in a custom Lua function by setting `setQueryCountFilter()`. This filter can decide whether to keep count on a query at all or rewrite for which query the counter will be increased. An example of a `QueryCountFilter` would be:

```lua
function filter(dq)
    qname = dq.qname:toString()

    -- don't count PTRs at all
    if (qname:match('in%-addr.arpa$')) then
        return false, ""
    end

    -- count these queries as if they were queried without leading www.
    if (qname:match('www.')) then
        qname = qname:gsub('www.', '')
    end

    -- count queries by default
    return true, qname
end

setQueryCountFilter(filter)
```

Valid return values for `QueryCountFilter` functions are:

- true: count the specified query
- false: don’t count the query

Note that the query counters are buffered and flushed each time statistics are sent to the carbon server. The current content of the buffer can be inspected with `getQueryCounters()`. If you decide to enable query counting
without `carbonServer()`, make sure you implement clearing the log from `maintenance()` by issuing `clearQueryCounters()`.
CHAPTER

NINE

WORKING WITH THE DNSDIST CONSOLE

dnsmasq can expose a commandline console over an encrypted tcp connection for controlling it, debugging DNS issues and retrieving statistics.

The console can be enabled with `controlSocket()`:

```plaintext
controlSocket('192.0.2.53:5199')
```

Enabling the console without encryption enabled is not recommended. Note that encryption requires building dnsmasq with either libssl or libcrypto support enabled.

Once you have a console-enabled dnsmasq, the first step to enable encryption is to generate a key with `makeKey()`:

```plaintext
$ ./dnsmasq -l 127.0.0.1:5300
[..]
> makeKey()
setKey("ENCODED KEY")
```

Then add the generated `setKey()` line to your dnsmasq configuration file, along with a `controlSocket()`:

```plaintext
controlSocket('192.0.2.53:5199') -- Listen on this IP and port for client connections
setKey("ENCODED KEY") -- Shared secret for the console
```

Now you can run `dnsmasq -c` to connect to the console. This makes dnsmasq read its configuration file and use the `controlSocket()` and `setKey()` statements to set up its connection to the server.

If you want to connect over the network, create a configuration file with the same two statements and run `dnsmasq -C /path/to/configfile -c`.

Alternatively, you can specify the address and key on the client commandline:

```plaintext
dnsmasq -k "ENCODED KEY" -c 192.0.2.53:5199
```

**Warning:** This will leak the key into your shell’s history and is **not** recommended.

Since 1.3.0, dnsmasq supports restricting which client can connect to the console with an ACL:

```plaintext
controlSocket('192.0.2.53:5199')
setConsoleACL('192.0.2.0/24')
```

The default value is ‘127.0.0.1’, restricting the use of the console to local users. Please make sure that encryption is enabled before using `addConsoleACL()` or `setConsoleACL()` to allow connection from remote clients. Even if the console is restricted to local users, the use of encryption is still strongly advised to prevent unauthorized local users from connecting to the console.
CHAPTER TEN

DNS-OVER-HTTP/3 (DOH3)

Note: This guide is about DNS over HTTP/3. For DNS over HTTP/1 and DNS over HTTP/2, please see DNS-over-HTTPS (DoH).

dnsdist supports DNS-over-HTTP/3 (DoH3) for incoming queries since 1.9.0. To see if the installation supports this, run `dnsdist --version`. If the output shows `dns-over-http3` incoming DNS-over-HTTP/3 is supported.

10.1 Incoming

Adding a listen port for DNS-over-HTTP/3 can be done with the `addDOH3Local()` function, e.g.:

```plaintext
addDOH3Local('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key')
```

This will make `dnsdist` listen on `[2001:db8:1:f00::1]:443` on UDP, and will use the provided certificate and key to serve incoming DoH3 connections.

The fourth parameter, if present, indicates various options. For instance, you can change the congestion control algorithm used. An example is:

```plaintext
addDOH3Local('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', {congestionControlAlgo="bbr"})
```

A particular attention should be taken to the permissions of the certificate and key files. Many ACME clients used to get and renew certificates, like CertBot, set permissions assuming that services are started as root, which is no longer true for dnsdist as of 1.5.0. For that particular case, making a copy of the necessary files in the `/etc/dnsdist` directory is advised, using for example CertBot’s `--deploy-hook` feature to copy the files with the right permissions after a renewal.

More information about sessions management can also be found in TLS Sessions Management.

10.1.1 Advertising DNS over HTTP/3 support

If DNS over HTTP/2 is also enabled in the configuration via `addDOHLocal()` (see DNS-over-HTTPS (DoH) for more information), it might be useful to advertise DNS over HTTP/3 support via the Alt-Svc header:

```plaintext
addDOHLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', "/dns", {customResponseHeaders={"alt-svc":"h3=":443"}}})
```

This will advertise that HTTP/3 is available on the same IP, port UDP/443.
DNS-OVER-HTTPS (DOH)

**Note:** This guide is about DNS over HTTP/1 and DNS over HTTP/2. For DNS over HTTP/3, please see DNS-over-HTTP/3 (DoH3)

dnsdist supports DNS-over-HTTPS (DoH, standardized in RFC 8484) for incoming queries since 1.4.0, and for outgoing queries since 1.7.0. To see if the installation supports this, run dnsdist --version. If the output shows dns-over-https(DOH) (dns-over-https(h2o nghttp2), dns-over-https(h2o) or dns-over-https(nghttp2) since 1.9.0), incoming DNS-over-HTTPS is supported. If outgoing-dns-over-https(nghttp2) shows up then outgoing DNS-over-HTTPS is supported.

### 11.1 Incoming

Adding a listen port for DNS-over-HTTPS can be done with the `addDOHLocal()` function, e.g.:

```plaintext
addDOHLocal('2001:db8:1::f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key')
```

This will make dnsdist listen on [2001:db8:1::f00::1]:443 on TCP, and will use the provided certificate and key to serve incoming TLS connections.

In order to support multiple certificates and keys, for example an ECDSA and an RSA one, the following syntax may be used instead:

```plaintext
addDOHLocal('2001:db8:1::f00::1', {'/etc/ssl/certs/example.com.rsa.pem', '/etc/ssl/certs/example.com.ecdsa.pem'}, {'/etc/ssl/private/example.com.rsa.key', '/etc/ssl/private/example.com.ecdsa.key'})
```

The certificate chain presented by the server to an incoming client will then be selected based on the algorithms this client advertised support for.

A fourth parameter may be added to specify the URL path(s) used by DoH. If you want your DoH server to handle `https://example.com/dns-query-endpoint`, you have to add `/dns-query-endpoint` to the call to `addDOHLocal()`. It is optional and defaults to / in 1.4.0, and /dns-query since 1.5.0.

The fifth parameter, if present, indicates various options. For instance, you use it to indicate custom HTTP headers. An example is:

```plaintext
addDOHLocal('2001:db8:1::f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', '/dns', {customResponseHeaders={['x-foo']="bar"}})
```

A more complicated (and more realistic) example is when you want to indicate metainformation about the server, such as the stated policy (privacy statement and so on). We use the link types of RFC 8631:

```plaintext
addDOHLocal('2001:db8:1::f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', '/dns', {customResponseHeaders={['link']="https://<example.com/policy.html> rel="service-meta"; type="text/html""}})
```

(continues on next page)
A particular attention should be taken to the permissions of the certificate and key files. Many ACME clients used to get and renew certificates, like CertBot, set permissions assuming that services are started as root, which is no longer true for dnsdist as of 1.5.0. For that particular case, making a copy of the necessary files in the /etc/dnsdist directory is advised, using for example CertBot’s --deploy-hook feature to copy the files with the right permissions after a renewal.

More information about sessions management can also be found in TLS Sessions Management.

11.1.1 Advertising DNS over HTTP/3 support

If DNS over HTTP/3 is also enabled in the configuration via addDOH3Local() (see DNS-over-HTTP/3 (DoH3) for more information), it might be useful to advertise this support via the Alt-Svc header:

```bash
addDOHLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/
private/example.com.key', '/dns', {customResponseHeaders={"alt-svc"="h3=":443
"}})
```

This will advertise that HTTP/3 is available on the same IP, port UDP/443.

11.1.2 Custom responses

It is also possible to set HTTP response rules to intercept HTTP queries early, before the DNS payload, if any, has been processed, to send custom responses including error pages, redirects or even serve static content. First a rule needs to be defined using newDOHResponseMapEntry(), then a set of rules can be applied to a DoH frontend via DOHFrontend:setResponsesMap(). For example, to send an HTTP redirect to queries asking for /rfc, the following configuration can be used:

```bash
.rfc8484") }
dohFE = getDOHFrontend(0)
dohFE:setResponsesMap(map)
```

11.1.3 DNS over HTTP

In case you want to run DNS-over-HTTPS behind a reverse proxy you probably don’t want to encrypt your traffic between reverse proxy and dnsdist. To let dnsdist listen for DoH queries over HTTP on localhost at port 8053 add one of the following to your config:

```bash
addDOHLocal("127.0.0.1:8053")
addDOHLocal("127.0.0.1:8053", nil, nil, "/", { reusePort=true })
```

11.1.4 HTTP/1 support

dnsdist initially relied on the h2o library to support incoming DNS over HTTPS. Since 1.9.0, h2o has been deprecated and nghttp2 is the preferred library for incoming DoH support, because h2o has unfortunately really never been maintained in a way that is suitable for use as a library (see https://github.com/h2o/h2o/issues/3230). While we took great care to make the migration as painless as possible, h2o supported HTTP/1 while nghttp2 does not. This is not an issue for actual DNS over HTTPS clients that support HTTP/2, but might be one in setups running dnsdist behind a reverse-proxy that does not support HTTP/2, like nginx. We do not plan on implementing HTTP/1, and recommend using HTTP/2 between the reverse-proxy and dnsdist for performance reasons. For nginx in particular, a possible work-around is to use the grpc_pass directive as suggested in their bug tracker.
11.1.5 Internal design

The internal design used for DoH handling uses two threads per `addDOHLocal()` directive. The first thread will handle the HTTP/2 communication with the client and pass the received DNS queries to a second thread which will apply the rules and pass the query to a backend, over UDP (except if the backend is TCP-only, or uses DNS over TLS, see the second schema below). The response will be received by the regular UDP response handler for that backend and passed back to the first thread. That allows the first thread to be low-latency dealing with TLS and HTTP/2 only and never blocking.

The fact that the queries are forwarded over UDP means that a large UDP payload size should be configured between dnsdist and the backend to avoid most truncation issues, and dnsdist will advise a 4096-byte UDP Payload Buffer size. UDP datagrams can still be larger than the MTU as long as fragmented datagrams are not dropped on the path between dnsdist and the backend. Since 1.7.0, truncated answers received over UDP for a DoH query will lead to a retry over TCP, passing the query to a TCP worker, as illustrated below.
11.1.6 Investigating issues

dnsdist provides a lot of counters to investigate issues:

- `showTCPStats()` will display a lot of information about current and passed connections
- `showTLSErrorCounters()` some metrics about why TLS sessions failed to establish
- `showDOHResponseCodes()` returns metrics about HTTP response codes sent by dnsdist

11.2 Outgoing

Support for securing the exchanges between dnsdist and the backend will be implemented in 1.7.0, and will lead to all queries, regardless of whether they were initially received by dnsdist over UDP, TCP, DoT or DoH, being forwarded over a secure DNS over HTTPS channel. That support can be enabled via the `dohPath` parameter of the `newServer()` command. Additional parameters control the TLS provider used (tls), the validation of the certificate presented by the backend (`caStore`, `validateCertificates`), the actual TLS ciphers used (`ciphers`, `ciphersTLS13`) and the SNI value sent (`subjectName`).

```
newServer({address="[2001:DB8::1]:443", tls="openssl", subjectName="doh.powerdns.com", dohPath="/dns-query", validateCertificates=true})
```

11.2.1 Internal design

The incoming queries, after the processing of rules if any, are passed to one of the DoH workers over a pipe. The DoH worker handles the communication with the backend, retrieves the response, and either responds directly to the client (queries coming over UDP) or pass it back over a pipe to the initial thread (queries coming over TCP, DoT or DoH). The number of outgoing DoH worker threads can be configured using `setOutgoingDoHWorkerThreads()`.
**DNS-OVER-QUIC (DOQ)**

**dnssdist** supports DNS-over-QUIC (DoQ, standardized in RFC 9250) for incoming queries since 1.9.0. To see if the installation supports this, run `dnssdist --version`. If the output shows `dns-over-quic incoming` DNS-over-QUIC is supported.

### 12.1 Incoming

Adding a listen port for DNS-over-QUIC can be done with the `addDOQLocal()` function, e.g.:

```
addDOQLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key')
```

This will make **dnssdist** listen on [2001:db8:1:f00::1]:853 on UDP, and will use the provided certificate and key to serve incoming DoQ connections.

The fourth parameter, if present, indicates various options. For instance, you can change the congestion control algorithm used. An example is:

```
addDOQLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', {congestionControlAlgo="bbr"})
```

A particular attention should be taken to the permissions of the certificate and key files. Many ACME clients used to get and renew certificates, like CertBot, set permissions assuming that services are started as root, which is no longer true for dnssdist as of 1.5.0. For that particular case, making a copy of the necessary files in the `/etc/dnssdist` directory is advised, using for example CertBot’s `--deploy-hook` feature to copy the files with the right permissions after a renewal.

More information about sessions management can also be found in *TLS Sessions Management*.
DNS-OVER-TLS

13.1 Incoming

Since version 1.3.0, `dnsdist` supports DNS-over-TLS for incoming queries. To see if the installation supports this, run `dnsdist --version`. If the output shows `dns-over-tls` with one or more SSL libraries in brackets, DNS-over-TLS is supported.

Adding a listen port for DNS-over-TLS can be done with the `addTLSLocal()` function, e.g.:

```
addTLSLocal('192.0.2.55', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key')
```

This will make `dnsdist` listen on 192.0.2.55:853 on TCP, and will use the provided certificate and key to serve incoming TLS connections.

In order to support multiple certificates and keys, for example an ECDSA and an RSA one, the following syntax may be used instead:

```
addTLSLocal('192.0.2.55', {'/etc/ssl/certs/example.com.rsa.pem', '/etc/ssl/certs/example.com.ecdsa.pem'}, {'/etc/ssl/private/example.com.rsa.key', '/etc/ssl/private/example.com.ecdsa.key'})
```

The certificate chain presented by the server to an incoming client will then be selected based on the algorithms this client advertised support for.

A particular attention should be taken to the permissions of the certificate and key files. Many ACME clients used to get and renew certificates, like CertBot, set permissions assuming that services are started as root, which is no longer true for `dnsdist` as of 1.5.0. For that particular case, making a copy of the necessary files in the `/etc/dnsdist` directory is advised, using for example CertBot’s `--deploy-hook` feature to copy the files with the right permissions after a renewal.

More information about sessions management can also be found in `TLS Sessions Management`.

13.2 Outgoing

Support for securing the exchanges between `dnsdist` and the backend will be implemented in 1.7.0, and will lead to all queries, regardless of whether they were initially received by `dnsdist` over UDP, TCP, DoT or DoH, being forwarded over a secure DNS over TLS channel. That support can be enabled via the `tls` parameter of the `newServer()` command. Additional parameters control the validation of the certificate presented by the backend (`caStore`, `validateCertificates`), the actual TLS ciphers used (`ciphers`, `ciphersTLS13`) and the SNI value sent (`subjectName`).

```
newServer({address="[2001:DB8::1]:853", tls="openssl", subjectName="dot.powerdns.com", validateCertificates=true})
```
13.3 Investigating issues

dnsdist provides a lot of counters to investigate issues:

- `showTCPStats()` will display a lot of information about current and passed connections
- `showTLSErrorCounters()` some metrics about why TLS sessions failed to establish
DNSCrypt

dnsdist, when compiled with `--enable-dnscrypt`, can be used as a DNSCrypt server, uncurving queries before forwarding them to downstream servers and curving responses back. To make dnsdist listen to incoming DNSCrypt queries on 127.0.0.1 port 8443, with a provider name of "2.providername", using a resolver certificate and associated key stored respectively in the resolver.cert and resolver.key files, the `addDNSCryptBind()` directive can be used:

```bash
addDNSCryptBind("127.0.0.1:8443", "2.providername", "/path/to/resolver.cert", "/path/to/resolver.key")
```

To generate the provider and resolver certificates and keys, you can simply do:

```bash
> generateDNSCryptProviderKeys("/path/to/providerPublic.key", "/path/to/

  → providerPrivate.key")
Provider fingerprint is:
> generateDNSCryptCertificate("/path/to/providerPrivate.key", "/path/to/resolver.

  → cert", "/path/to/resolver.key", serial, validFrom, validUntil)
```

Ideally, the certificates and keys should be generated on an offline dedicated hardware and not on the resolver. The resolver key should be regularly rotated and should never touch persistent storage, being stored in a tmpfs with no swap configured.

You can display the currently configured DNSCrypt binds with:

```bash
> showDNSCryptBinds()
# Address  Provider Name  Serial  Validity  Provider fingerprint
  127.0.0.1:8443  2.name  14  2016-04-10 08:14:15 0  
```

If you forgot to write down the provider fingerprint value after generating the provider keys, you can use `printDNSCryptProviderFingerprint()` to retrieve it later:

```bash
> printDNSCryptProviderFingerprint("/path/to/providerPublic.key")
Provider fingerprint is:
```
CHAPTER
FIFTEEN

CONFIGURING DOWNSTREAM SERVERS

As dnsdist is a loadbalancer and does not do any DNS resolving or serving by itself, it needs downstream servers. To add downstream servers, either include them on the command line:

```
dnsdist -l 130.161.252.29 -a 130.161.0.0/16 8.8.8.8 208.67.222.222 2620:0:ccc::2 → 2620:0:ccd::2
```

Or add them to the configuration file:

```
setLocal("130.161.252.29:53")
setACL("130.161.0.0/16")
newServer("8.8.8.8")
newServer("208.67.222.222")
newServer("2620:0:ccc::2")
newServer("2620:0:ccd::2")
```

These two equivalent configurations give you sane load balancing using a very sensible distribution policy. Many users will simply be done with this configuration. It works as well for authoritative as for recursive servers.

15.1 Healthcheck

dnsdist uses health-check queries, sent once every second, to determine the availability of a backend server. Since 1.8.0, it also supports a lazy health-checking mode which only sends active health-check queries after a configurable threshold of regular queries have failed, see below.

By default, an A query for the "a.root-servers.net." name is sent. A different query type, class and target can be specified by passing, respectively, the checkType, checkClass and checkName parameters to `newServer()`. The interval between two health-check queries can be set via the checkInterval interval parameter, and the amount of time for a response to be received via the checkTimeout one.

Since the 1.3.0 release, the checkFunction option is also supported, taking a Lua function as parameter. This function receives a DNSName, two integers and a DNSHeader object (DNSHeader (dh) object) representing the QName, QType and QClass of the health check query as well as the DNS header, as they are defined before the function was called. The function must return a DNSName and two integers representing the new QName, QType and QClass, and can directly modify the DNSHeader object.

The following example sets the CD flag to true and change the QName to "powerdns.com." and the QType to AAAA while keeping the initial QClass.

```
function myHealthCheck(qname, qtype, qclass, dh)
  dh:setCD(true)
  return newDNSName("powerdns.com."), DNSQType.AAAA, qclass
end

newServer({address="2620:0:ccd::2", checkFunction=myHealthCheck})
```
The default behavior is to consider any valid response with an RCODE different from ServFail as valid. If the mustResolve parameter of newServer() is set to true, a response will only be considered valid if its RCODE differs from NXDomain, ServFail and Refused.

The number of health check failures before a server is considered down is configurable via the maxCheckFailures parameter, defaulting to 1. In the same way, the number of consecutive successful health checks needed for a server to be considered available can be set via the rise parameter, defaulting to 1.

The CD flag can be set on the query by setting setCD to true. e.g.:
```
newServer({address="192.0.2.1", checkType="AAAA", checkClass=DNSClass.CHAOS, checkName="a.root-servers.net.", mustResolve=true})
```

You can turn on logging of health check errors using the setVerboseHealthChecks() function.

### 15.1.1 Lazy health-checking

In some setups, especially on low-end devices, it might not make sense to actively send queries to the backend at a regular interval. Using the feedback from the results of regular queries can instead be used to infer if a backend might not be working properly.

Since 1.8.0, dnsdist implements a lazy mode that can be set via the healthCheckMode option on newServer(). In this mode, dnsdist will only send active health-check queries after seeing a configurable amount of regular queries failing. It will then place the backend in a PotentialFailure state, from the initial Healthy one, and send health-check queries every checkInterval seconds. If maxCheckFailures of these fail, the backend is then moved to a Failed state and marked as down, and active health-check queries are sent every lazyHealthCheckFailedInterval seconds. After rise successful, consecutive queries, the backend will be moved back to the Healthy state and marked as up again, and health-check queries will stop.

The threshold of failed regular queries is configured via lazyHealthCheckThreshold, indicating of percentage of regular queries that should have resulted in a failure over the last recent queries. Only the results of the last lazyHealthCheckSampleSize queries will be considered, as the results are kept in a in-memory circular buffer. The results of at least lazyHealthCheckMinSampleCount queries should be present for the threshold to be considered meaningful, to avoid an issue with a too small sample.
By default both queries that resulted in a timeout and those that received a ServFail answer are considered failures, but it is possible to set lazyHealthCheckMode to TimeoutOnly so that only timeouts are considered failures.

So for example, if we set healthCheckMode to lazy, lazyHealthCheckSampleSize to 100, lazyHealthCheckMinSampleCount to 10, lazyHealthCheckThreshold to 30, maxCheckFailures to 2 and rise to 2:

- nothing will happen until at least 10 queries have been received
- only the results of the last 100 queries will be considered
- if at least 30 of these last 100 have failed, the threshold will be reached and active health-check queries will be sent every checkInterval seconds
- if the health-check query is successful, the backend will stay up and no more query will be sent
- but if instead two consecutive queries fail, the backend will be marked as down and health-check queries will be sent every lazyHealthCheckFailedInterval seconds
- it will take two consecutive, successful health-checks for the backend to go back to Healthy and be marked up again

```.
newServer({address="192.0.2.1", healthCheckMode='lazy', checkInterval=1, 
  lazyHealthCheckFailedInterval=30, rise=2, maxCheckFailures=3, 
  lazyHealthCheckThreshold=30, lazyHealthCheckSampleSize=100, 
  lazyHealthCheckMinSampleCount=10, lazyHealthCheckMode='TimeoutOnly'})
```

The ‘lazy’ mode also supports using an exponential back-off time between health-check queries, once a backend has been moved to the ‘down’ state. This can be enabled by setting the lazyHealthCheckUseExponentialBackOff parameter to ‘true’. Once the backend has been marked as ‘down’, the first query will be sent after lazyHealthCheckFailedInterval seconds, the second one after 2 times lazyHealthCheckFailedInterval seconds, the third after 4 times lazyHealthCheckFailedInterval seconds, and so on and so forth, until lazyHealthCheckMaxBackOff has been reached. Then probes will be sent every lazyHealthCheckMaxBackOff seconds (default is 3600 so one hour) until the backend comes ‘up’ again.

15.2 Source address selection

In multi-homed setups, it can be useful to be able to select the source address or the outgoing interface used by dnsdist to contact a downstream server. This can be done by using the source parameter:

```.
newServer({address="192.0.2.1", source="192.0.2.127"})
newServer({address="192.0.2.1", source="eth1"})
newServer({address="192.0.2.1", source="192.0.2.127@eth1"})
```

The supported values for source are:

- an IPv4 or IPv6 address, which must exist on the system
- an interface name
- an IPv4 or IPv6 address followed by ‘@’ then an interface name

Please note that specifying the interface name is only supported on system having IP_PKTINFO.
15.3 Securing the channel

15.4 Securing the path to the backend

As explained briefly in the quickstart guide, dnsdist has always been designed as a load-balancer placed in front of authoritative or recursive servers, assuming that the network path between dnsdist and these servers is trusted. This is particularly important because for performance reasons it uses a single connected socket for UDP exchanges by default, and easy to predict DNS query IDs, which makes it easy for an attacker to poison responses.

If dnsdist is instead intended to be deployed in such a way that the path to its backend is not secure, the UDP protocol should not be used, and ‘TCP-only’, DNS over TLS and DNS over HTTPS protocols used instead, as supported since 1.7.0.

Using these protocols leads to all queries, regardless of whether they were initially received by dnsdist over UDP, TCP, DoT or DoH, being forwarded over a TCP socket, a secure DNS over TLS channel or a secure DNS over HTTPS channel.

The TCP-only mode for a backend can be enabled by using the tcpOnly parameter of the newServer() command.

The DNS over TLS mode via the tls parameter of the newServer() command. Additional parameters control the validation of the certificate presented by the backend (caStore, validateCertificates), the actual TLS ciphers used (ciphers, ciphersTLS13) and the SNI value sent (subjectName).

The DNS over HTTPS mode in the same way than DNS over TLS but with the additional dohPath keyword indicating that DNS over HTTPS should be used instead of DNS over TLS.

If it is absolutely necessary to support UDP exchanges over an untrusted network, a few options have been introduced in 1.8.0 to make spoofing attempts harder:

- setRandomizedIdsOverUDP() will randomize the IDs in outgoing queries, at a small performance cost. setMaxUDPOutstanding() should be set at its highest possible value (default since 1.4.0) to make that setting fully efficient.
- setRandomizedOutgoingSockets() can be used to randomize the outgoing socket used when forwarding a query to a backend. This requires configuring the backend to use more than one outgoing socket via the sockets parameter of newServer() to be of any use.
Dynamic Blocks can be seen as short-lived rules, automatically inserted based on configurable thresholds and the analysis of recently received traffic, and automatically removed after a configurable amount of time.

The analyzed traffic is the one kept by dnsdist in its in-memory ring buffers. The number of entries kept in these ring buffers can be set via the `setRingBuffersSize()` directive, and the impact in terms of CPU and memory consumption is described in *Performance Tuning*.

That number of entries is crucial for the rate-based rules, like `DynBlockRulesGroup:setQueryRate()`, as they will never match if the number of entries in the ring buffer is too small for the required rate, as explained in more details below.

To set dynamic rules, based on recent traffic, define a function called `maintenance()` in Lua. It will get called every second, and from this function you can set rules to block traffic based on statistics. More exactly, the thread handling the `maintenance()` function will sleep for one second between each invocation, so if the function takes several seconds to complete it will not be invoked exactly every second.

As an example:

```lua
local dbr = dynBlockRulesGroup()
dbr:setQueryRate(20, 10, "Exceeded query rate", 60)

function maintenance()
    dbr:apply()
end
```

This will dynamically block all hosts that exceeded 20 queries/s as measured over the past 10 seconds, and the dynamic block will last for 60 seconds.

`DynBlockRulesGroup` is a very efficient way of processing dynamic blocks that was introduced in 1.3.0. Before that, it was possible to use `addDynBlocks()` instead:

```lua
-- this is a legacy method, please see above for DNSdist >= 1.3.0
function maintenance()
    addDynBlocks(exceedQRate(20, 10), "Exceeded query rate", 60)
end
```

Dynamic blocks in force are displayed with `showDynBlocks()` and can be cleared with `clearDynBlocks()`. They return a table whose key is a `ComboAddress` object, representing the client’s source address, and whose value is an integer representing the number of queries matching the corresponding condition (for example the qtype for `exceedQTypeRate()`), rcode for `exceedServFails()`).

All exceed-functions are documented in the *Configuration Reference*.

Dynamic blocks drop matched queries by default, but this behavior can be changed with `setDynBlocksAction()`. For example, to send a REFUSED code instead of dropping the query:

```lua
setDynBlocksAction(DNSAction.Refused)
```

Please see the documentation for `setDynBlocksAction()` to confirm which actions are supported.
### 16.1 DynBlockRulesGroup

Starting with dnssit 1.3.0, a new DynBlockRulesGroup function can be used to return a DynBlockRulesGroup instance, designed to make the processing of multiple rate-limiting rules faster by walking the query and response buffers only once for each invocation, instead of once per existing exceed*() invocation.

The new syntax would be:

```lua
local dbr = dynBlockRulesGroup()
dbr:setQueryRate(30, 10, "Exceeded query rate", 60)
dbr:setRCodeRate(DNSRCode.NXDOMAIN, 20, 10, "Exceeded NXD rate", 60)
dbr:setRCodeRate(DNSRCode.SERVFAIL, 20, 10, "Exceeded ServFail rate", 60)
dbr:setQTypeRate(DNSQType.ANY, 5, 10, "Exceeded ANY rate", 60)
dbr:setResponseByteRate(10000, 10, "Exceeded resp BW rate", 60)

function maintenance()
    dbr:apply()
end
```

Before 1.3.0 the legacy syntax was:

```lua
function maintenance()
    -- this example is using legacy methods, please see above for DNSdist >= 1.3.0
    addDynBlocks(exceedQRate(30, 10), "Exceeded query rate", 60)
    addDynBlocks(exceedNXDOMAINs(20, 10), "Exceeded NXD rate", 60)
    addDynBlocks(exceedServFails(20, 10), "Exceeded ServFail rate", 60)
    addDynBlocks(exceedQTypeRate(DNSQType.ANY, 5, 10), "Exceeded ANY rate", 60)
    addDynBlocks(exceedRespByterate(1000000, 10), "Exceeded resp BW rate", 60)
end
```

The old syntax would walk the query buffer 2 times and the response one 3 times, while the new syntax does it only once for each. It also reuse the same internal table to keep track of the source IPs, reducing the CPU usage.

DynBlockRulesGroup also offers the ability to specify that some network ranges should be excluded from dynamic blocking:

```lua
-- do not add dynamic blocks for hosts in the 192.0.2.0/24 and 2001:db8::/32 ranges
-- except for 192.0.2.1
local dbr = dynBlockRulesGroup()
dbr:excludeRange({'192.0.2.0/24', "2001:db8::/32"})
dbr:includeRange("192.0.2.1/32")
```

Since 1.3.3, it’s also possible to define a warning rate. When the query or response rate raises above the warning level but below the trigger level, a warning message will be issued along with a no-op block. If the rate reaches the trigger level, the regular action is applied.

```lua
local dbr = dynBlockRulesGroup()
-- Generate a warning if we detect a query rate above 100 qps for at least 10s.
-- If the query rate raises above 300 qps for 10 seconds, we'll block the client.
-- For 60s.
    dbr:setQueryRate(300, 10, "Exceeded query rate", 60, DNSAction.Drop, 100)
```

Since 1.6.0, if a default eBPF filter has been set via `setDefaultBPFFilter()` dnssit will automatically try to use it when a “drop” dynamic block is inserted via a DynBlockRulesGroup. eBPF blocks are applied in kernel space and are much more efficient than user space ones. Note that a regular block is also inserted so that any failure will result in a regular block being used instead of the eBPF one.

### 16.2 Rate rules and size of the ring buffers

As explained in the introduction, the whole dynamic block feature is based on analyzing the recent traffic kept in dnssit’s in-memory ring buffers, whose content can be inspected via `grepq()`.
The sizing of the buffers, in addition to having performance impacts explained in *Performance Tuning*, directly impacts some of the dynamic block rules, like the rate and ratio-based ones.

For example, if `DynBlockRulesGroup:setQueryRate()` is used to request the blocking for 60s of any client exceeding 1000 qps over 10s, like this:

```lua
dbr:setQueryRate(1000, 10, "Exceeded query rate", 60, DNSAction.Drop)
```

For this rule to trigger, dnsdist will need to scan the ring buffers and find 1000 * 10 = 10000 queries, not older than 10s, from that client. Since a ring buffer has a fixed size, and new entries override the oldest ones when the buffer is full, that only works if there are enough entries in the buffer.

This is even more obvious for the ratio-based rules, when they have a minimum number of responses set, because in that case they clearly require that number of responses to fit in the buffer.

That requirement could be lifted a bit by the use of sampling, meaning that only one query out of 10 would be recorded, for example, and the total amount would be inferred from the queries present in the buffer. As of 1.7.0, sampling as unfortunately not been implemented yet.
These chapters contain several guides and nuggets of information regarding dnsdist operation and accomplishing specific goals.

17.1 Built-in webserver

To visually interact with dnsdist, try adding `webserver()` and `setWebserverConfig()` directives to the configuration:

```plaintext
text
webserver("127.0.0.1:8083")
setWebserverConfig({password="supersecretpassword", apiKey="supersecretAPIkey"})
```

Now point your browser at http://127.0.0.1:8083 and log in with any username, and that password. Enjoy!

Since 1.5.0, only connections from 127.0.0.1 and ::1 are allowed by default. To allow connections from 192.0.2.0/24 but not from 192.0.2.1, instead:

```plaintext
text
setWebserverConfig({password="supersecretpassword", apiKey="supersecretAPIkey",←
→acl="192.0.2.0/24, !192.0.2.1"})
```

17.1.1 Security of the Webserver

The built-in webserver serves its content from inside the binary, this means it will not and cannot read from disk. By default, our web server sends some security-related headers:

```
X-Content-Type-Options: nosniff
X-Frame-Options: deny
X-Permitted-Cross-Domain-Policies: none
X-XSS-Protection: 1; mode=block
Content-Security-Policy: default-src 'self'; style-src 'self' 'unsafe-inline'
```

You can override those headers, or add custom headers by using the last parameter to `setWebserverConfig()`. For example, to remove the X-Frame-Options header and add a X-Custom one:

```plaintext
text
setWebserverConfig({password="supersecretpassword", apiKey="supersecretAPIkey",←
→customHeaders={"X-Frame-Options"= "", ["X-Custom"]="custom"}})
```

Credentials can be changed at run time using the `setWebserverConfig()` function.

17.1.2 dnsdist API

To access the API, the `apikey` must be set in the `setWebserverConfig()` function. Use the API, this key will need to be sent to dnsdist in the `X-API-Key` request header. An HTTP 401 response is returned when a wrong or
no API key is received. A 404 response is generated if the requested endpoint does not exist. And a 405 response is returned when the HTTP method is not allowed.

**URL Endpoints**

**GET /jsonstat**

Get statistics from dnsdist in JSON format. The `Accept` request header is ignored. This endpoint accepts a command query for different statistics:

- `stats`: Get all **Statistics** as a JSON dict
- `dynblocklist`: Get all current **dynamic blocks**, keyed by netmask
- `ebpfblocklist`: Idem, but for **eBPF** blocks

**Example request:**

```
GET /jsonstat?command=stats HTTP/1.1
Host: example.com
Accept: application/json, text/javascript
```

**Example response:**

```
HTTP/1.1 200 OK
Transfer-Encoding: chunked
Connection: close
Content-Security-Policy: default-src 'self'; style-src 'self' 'unsafe-inline'
Content-Type: application/json
X-Content-Type-Options: nosniff
X-Frame-Options: deny
X-Permitted-Cross-Domain-Policies: none
X-Xss-Protection: 1; mode=block

17.1. Built-in webserver 95
Example Prometheus configuration:

This is just the scrape job description, for details see the Prometheus documentation.

```
job_name: dnsdist
scrape_interval: 10s
scrape_timeout: 2s
metrics_path: /metrics
basic_auth:
```

(continues on next page)
用品名和密码登录

```
username: dontcare
password: yoursecret
```

**DELETE /api/v1/cache?pool=<pool-name>&name=<dns-name>[&type=<dns-type>][&suffix=]**

New in version 1.8.0.

Allows removing entries from a cache. The pool to which the cache is associated should be specified in the pool parameter, and the name to remove in the name parameter. By default only entries matching the exact name will be removed, but it is possible to remove all entries below that name by passing the suffix parameter set to any value. By default entries for all types for the name are removed, but it is possible to only remove entries for a specific type by passing the type parameter set to the requested type. Supported values are DNS type names as a strings (AAAA), or numerical values (as either #64 or TYPE64).

**Example request:**

```
DELETE /api/v1/cache?pool=&name=free.fr HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Connection: keep-alive
Content-Length: 0
Host: localhost:8080
X-API-Key: supersecretAPIkey
```

**Example response:**

```
HTTP/1.1 200 OK
Connection: close
Content-Security-Policy: default-src 'self'; style-src 'self' 'unsafe-inline'
Content-Type: application/json
Transfer-Encoding: chunked
X-Content-Type-Options: nosniff
X-Frame-Options: deny
X-Permitted-Cross-Domain-Policies: none
X-Xss-Protection: 1; mode=block
{
   "count": "1",
   "status": "purged"
}
```

**GET /api/v1/servers/localhost**

Get a quick overview of several parameters.

**Response JSON Object**

- acl\((string)\) – A string of comma-separated netmasks currently allowed by the ACL.
- cache-hit-response-rules\((list)\) – A list of ResponseRule objects applied on cache hits
- selfanswered-response-rules\((list)\) – A list of ResponseRule objects applied on self-answered queries
- daemon_type\((string)\) – The type of daemon, always “dnsdist”
- frontends\((list)\) – A list of Frontend objects
- pools\((list)\) – A list of Pool objects
- response-rules\((list)\) – A list of ResponseRule objects
- rules\((list)\) – A list of Rule objects
servers (list) – A list of Server objects

version (string) – The running version of dnsdist

GET /api/v1/servers/localhost/statistics
Returns a list of all statistics as StatisticItem.

GET /api/v1/servers/localhost/config
Returns a list of ConfigSetting objects.

GET /api/v1/servers/localhost/config/allow-from
Gets you the allow-from ConfigSetting, who's value is a list of strings of all the netmasks in the ACL.

Example request:
```
GET /api/v1/servers/localhost/config/allow-from HTTP/1.1
X-API-Key: supersecretAPIkey
```

Example response:
```
HTTP/1.1 200 OK
Connection: close
Content-Type: application/json
Transfer-Encoding: chunked
X-Content-Type-Options: nosniff
X-Frame-Options: deny
X-Permitted-Cross-Domain-Policies: none
X-Xss-Protection: 1; mode=block
{
  "name": "allow-from",
  "type": "ConfigSetting",
  "value": [
    "fc00::/7",
    "169.254.0.0/16",
    "100.64.0.0/10",
    "fe80::/10",
    "10.0.0.0/8",
    "127.0.0.0/8",
    ":1/128",
    "172.16.0.0/12",
    "192.168.0.0/16"
  ]
}
```

PUT /api/v1/servers/localhost/config/allow-from
Allows you to update the allow-from ACL with a list of netmasks.

Make sure you made the API writable using setAPIWritable(). Changes to the ACL are directly applied, no restart is required.

Example request:
```
PUT /api/v1/servers/localhost/config/allow-from HTTP/1.1
Content-Length: 37
Content-Type: application/json
X-API-Key: supersecretAPIkey
{
  "value": [
    "fc00::/7",
    "169.254.0.0/16",
    "100.64.0.0/10",
    "fe80::/10",
    "10.0.0.0/8",
    "127.0.0.0/8",
    ":1/128",
    "172.16.0.0/12",
    "192.168.0.0/16"
  ]
}
```
Example response:

```
HTTP/1.1 200 OK
Connection: close
Content-Security-Policy: default-src 'self'; style-src 'self' 'unsafe-inline'
Content-Type: application/json
Transfer-Encoding: chunked
X-Content-Type-Options: nosniff
X-Frame-Options: deny
X-Permitted-Cross-Domain-Policies: none
X-Xss-Protection: 1; mode=block

{
  "name": "allow-from",
  "type": "ConfigSetting",
  "value": [
    "127.0.0.0/8",
    "::1/128"
  ]
}
```

**GET /api/v1/servers/localhost/pool?name=pool-name**

New in version 1.6.1.

Get a quick overview of the pool named “pool-name”.

**Response JSON Object**

- **list** – A list of metrics related to that pool
- **servers** (list) – A list of Server objects present in that pool

**GET /api/v1/servers/localhost/rings?maxQueries=NUM&maxResponses=NUM**

New in version 1.9.0.

Get the most recent queries and responses from the in-memory ring buffers. Returns up to maxQueries query entries if set, up to maxResponses responses if set, and the whole content of the ring buffers otherwise.

**Response JSON Object**

- **queries** (list) – The list of the most recent queries, as RingEntry objects
- **responses** (list) – The list of the most recent responses, as RingEntry objects

**JSON Objects**

**ConfigSetting**

An object representing a global configuration element. The following configuration are returned:

- **acl** The currently configured ACLs
- **control-socket** The currently configured console address
- **ecs-override**
- **ecs-source-prefix-v4** The currently configured setECSSourcePrefixV4()
**dnsdist**

- `ecs-source-prefix-v6` The currently configured `setECSSourcePrefixV6()`
- `fixup-case`
- `max-outstanding`
- `server-policy` The currently set *Loadbalancing and Server Policies*
- `stale-cache-entries-ttl`
- `tcp-recv-timeout`
- `tcp-send-timeout`
- `truncate-tc`
- `verbose`
- `verbose-health-checks` The currently configured `setVerboseHealthChecks()`

**Object Properties**

- `name (string)` – The name of the setting
- `type (string)` – “ConfigSetting”
- `value (string)` – The value for this setting

**DoHFrontend**

A description of a DoH bind dnsdist is listening on.

**Object Properties**

- `bad-requests (integer)` – Number of requests that could not be converted to a DNS query
- `error-responses (integer)` – Number of HTTP responses sent with a non-200 code
- `get-queries (integer)` – Number of DoH queries received via the GET HTTP method
- `http-connects (integer)` – Number of DoH TCP connections established to this frontend
- `http1-queries (integer)` – Number of DoH queries received over HTTP/1
- `http1-x00-responses (integer)` – Number of DoH responses sent, over HTTP/1, per response code (200, 400, 403, 500, 502)
- `http1-other-responses (integer)` – Number of DoH responses sent, over HTTP/1, with another response code
- `http2-queries (integer)` – Number of DoH queries received over HTTP/2
- `http2-x00-responses (integer)` – Number of DoH responses sent, over HTTP/2, per response code (200, 400, 403, 500, 502)
- `http2-other-responses` – Number of DoH responses sent, over HTTP/2, with another response code
- `post-queries (integer)` – Number of DoH queries received via the POST HTTP method
- `redirect-responses (integer)` – Number of HTTP redirect responses sent
- `valid-responses (integer)` – Number of valid DoH (2xx) responses sent

**Frontend**

A description of a bind dnsdist is listening on.

**Object Properties**
• **address** *(string)* – IP and port that is listened on

• **id** *(integer)* – Internal identifier

• **nonCompliantQueries** *(integer)* – Amount of non-compliant queries received by this frontend

• **queries** *(integer)* – The number of received queries on this bind

• **responses** *(integer)* – Amount of responses sent by this frontend

• **tcp** *(boolean)* – true if this is a TCP bind

• **tcpAvgConnectionDuration** *(integer)* – The average duration of a TCP connection (ms)

• **tcpAvgQueriesPerConnection** *(integer)* – The average number of queries per TCP connection

• **tcpClientTimeouts** *(integer)* – Amount of TCP connections terminated by a timeout while reading from the client

• **tcpCurrentConnections** *(integer)* – Amount of current incoming TCP connections from clients

• **tcpDiedReadingQuery** *(integer)* – Amount of TCP connections terminated while reading the query from the client

• **tcpDiedSendingResponse** *(integer)* – Amount of TCP connections terminated while sending a response to the client

• **tcpDownstreamTimeouts** *(integer)* – Amount of TCP connections terminated by a timeout while reading from the backend

• **tcpGaveUp** *(integer)* – Amount of TCP connections terminated after too many attempts to get a connection to the backend

• **tcpMaxConcurrentConnections** *(integer)* – Maximum number of concurrent incoming TCP connections from clients

• **tls10Queries** *(integer)* – Number of queries received by dnsdist over TLS 1.0

• **tls11Queries** *(integer)* – Number of queries received by dnsdist over TLS 1.1

• **tls12Queries** *(integer)* – Number of queries received by dnsdist over TLS 1.2

• **tls13Queries** *(integer)* – Number of queries received by dnsdist over TLS 1.3

• **tlsHandshakeFailuresDHKeyTooSmall** *(integer)* – Amount of TLS connections where the client has negotiated a not strong enough diffie-hellman key during the TLS handshake

• **tlsHandshakeFailuresInappropriateFallBack** *(integer)* – Amount of TLS connections where the client tried to negotiate an invalid, too old, TLS version

• **tlsHandshakeFailuresNoSharedCipher** *(integer)* – Amount of TLS connections were no cipher shared by both the client and the server could been found during the TLS handshake

• **tlsHandshakeFailuresUnknownCipher** *(integer)* – Amount of TLS connections where the client has tried to negotiate an unknown cipher

• **tlsHandshakeFailuresUnknownExchangeType** *(integer)* – Amount of TLS connections where the client has tried to negotiate an unknown TLS exchange mechanism

• **tlsHandshakeFailuresUnknownProtocol** *(integer)* – Amount of TLS connections where the client has tried to negotiate an unknown TLS version

• **tlsHandshakeFailuresUnsupportedEC** *(integer)* – Amount of TLS connections where the client has tried to negotiate an unsupported elliptic curve
• `tlsHandshakeFailuresUnsupportedProtocol` (`integer`) – Amount of TLS connections where the client has tried to negotiate a unsupported TLS version

• `tlsInactiveTicketKey` (`integer`) – Amount of TLS sessions resumed from an inactive key

• `tlsNewSessions` (`integer`) – Amount of new TLS sessions negotiated

• `tlsResumptions` (`integer`) – Amount of TLS sessions resumed

• `tlsUnknownQueries` (`integer`) – Number of queries received by dnsdist over an unknown TLS version

• `tlsUnknownTicketKey` (`integer`) – Amount of attempts to resume TLS session from an unknown key (possibly expired)

• `type` (`string`) – UDP, TCP, DoT or DoH

• `udp` (`boolean`) – true if this is a UDP bind

Pool
A description of a pool of backend servers.

Object Properties

• `id` (`integer`) – Internal identifier

• `cacheCleanupCount` (`integer`) – Number of times that cache was scanned for expired entries, or just to remove entries because it is full

• `cacheDeferredInserts` (`integer`) – The number of times an entry could not be inserted in the associated cache, if any, because of a lock

• `cacheDeferredLookups` (`integer`) – The number of times an entry could not be looked up from the associated cache, if any, because of a lock

• `cacheEntries` (`integer`) – The current number of entries in the associated cache, if any

• `cacheHits` (`integer`) – The number of cache hits for the associated cache, if any

• `cacheInsertCollisions` (`integer`) – The number of times an entry could not be inserted into the cache because a different entry with the same hash already existed

• `cacheLookupCollisions` (`integer`) – The number of times an entry retrieved from the cache based on the query hash did not match the actual query

• `cacheMisses` (`integer`) – The number of cache misses for the associated cache, if any

• `cacheSize` (`integer`) – The maximum number of entries in the associated cache, if any

• `cacheTTLTooShorts` (`integer`) – The number of times an entry could not be inserted into the cache because its TTL was set below the minimum threshold

• `name` (`string`) – Name of the pool

• `serversCount` (`integer`) – Number of backends in this pool

Rule
This represents a policy that is applied to queries

Object Properties

• `action` (`string`) – The action taken when the rule matches (e.g. “to pool abuse”)

• `action-stats` (`dict`) – A list of statistics whose content varies depending on the kind of rule

• `creationOrder` (`integer`) – The order in which a rule has been created, mostly used for automated tools
dnsdist

• **id (integer)** – The position of this rule
• **matches (integer)** – How many times this rule was hit
• **name (string)** – The name assigned to this rule by the administrator, if any
• **rule (string)** – The matchers for the packet (e.g. “qname==bad-domain1.example., bad-domain2.example.”)
• **uuid (string)** – The UUID of this rule

**ResponseRule**
This represents a policy that is applied to responses

**Object Properties**

• **action (string)** – The action taken when the rule matches (e.g. “drop”)
• **id (integer)** – The identifier (or order) of this rule
• **matches (integer)** – How many times this rule was hit
• **rule (string)** – The matchers for the packet (e.g. “qname==bad-domain1.example., bad-domain2.example.”)

**Server**
This object represents a backend server.

**Object Properties**

• **address (string)** – The remote IP and port
• **id (integer)** – Internal identifier
• **latency (integer)** – The current latency of this backend server for UDP queries, in milliseconds
• **name (string)** – The name of this server
• **integer** – nonCompliantResponses: Amount of non-compliant responses
• **order (integer)** – Order number
• **outstanding (integer)** – Number of currently outstanding queries
• **pools ([string])** – The pools this server belongs to
• **protocol (string)** – The protocol used by this server (Do53, DoT, DoH)
• **qps (integer)** – The current number of queries per second to this server
• **qpsLimit (integer)** – The configured maximum number of queries per second
• **queries (integer)** – Total number of queries sent to this backend
• **responses (integer)** – Amount of responses received from this server
• **reuseds (integer)** – Number of queries for which a response was not received in time
• **sendErrors (integer)** – Number of network errors while sending a query to this server
• **state (string)** – The state of the server (e.g. “DOWN” or “up”)
• **tcpAvgConnectionDuration (integer)** – The average duration of a TCP connection (ms)
• **tcpAvgQueriesPerConnection (integer)** – The average number of queries per TCP connection
• **tcpConnectTimeouts (integer)** – The number of TCP connect timeouts
• **tcpCurrentConnections (integer)** – The number of current TCP connections

17.1. Built-in webserver
• tcpDiedReadingResponse (integer) – The number of TCP I/O errors while reading the response

• tcpDiedSendingQuery (integer) – The number of TCP I/O errors while sending the query

• tcpGaveUp (integer) – The number of TCP connections failing after too many attempts

• tcpLatency (integer) – Server’s latency when answering TCP questions in milliseconds

• tcpMaxConcurrentConnections (integer) – The maximum number of concurrent TCP connections

• tcpNewConnections (integer) – The number of established TCP connections in total

• tcpReadTimeouts (integer) – The number of TCP read timeouts

• tcpReusedConnections (integer) – The number of times a TCP connection has been reused

• tcpTooManyConcurrentConnections (integer) – Number of times we had to enforce the maximum number of concurrent TCP connections

• tcpWriteTimeouts (integer) – The number of TCP write timeouts

• tlsResumptions (integer) – The number of times a TLS session has been resumed

• weight (integer) – The weight assigned to this server

• dropRate (float) – The amount of packets dropped (timing out) per second by this server

• healthCheckFailures (integer) – Number of health check attempts that failed (total)

• healthCheckFailureParsing (integer) – Number of health check attempts that failed because the payload could not be parsed

• healthCheckFailureTimeout (integer) – Number of health check attempts that failed because the response was not received in time

• healthCheckFailureNetwork (integer) – Number of health check attempts that failed because of a network error

• healthCheckFailureMismatch (integer) – Number of health check attempts that failed because the ID, qname, qtype or qclass did not match

• healthCheckFailureInvalid (integer) – Number of health check attempts that failed because the DNS response was not valid

StatisticItem
This represents a statistics element.

Object Properties

• name (string) – The name of this statistic. See Statistics

• type (string) – “StatisticItem”

• value (integer) – The value for this item

RingEntry
This represents an entry in the in-memory ring buffers.

Object Properties

• age (float) – How long ago was the query or response received, in seconds
**17.2 Server pools**

dnsdist has the concept to “server pools”, any number of servers can belong to a group. A default pool, identified by the empty string ‘ ’ is always present, and newServer without a pool argument will assign the new server to that pool.

Let’s say we know we’re getting a whole bunch of traffic for a domain used in DoS attacks, for example ‘example.com’. We can do two things with this kind of traffic. Either we block it outright, like this:

```
addAction("bad-domain.example.", DropAction())
```

Or we configure a server pool dedicated to receiving the nasty stuff:

```
newServer({address="192.0.2.3", pool="abuse"})
-- Add a backend server
    -- with address 192.0.2.3 and assign it to the "abuse" pool
addAction({'bad-domain1.example', 'bad-domain2.example.'}, PoolAction("abuse"))
    -- Send all queries for "bad-domain1.example." and "bad-domain2.example" to the
    -- "abuse" pool
```

The wonderful thing about this last solution is that it can also be used for things where a domain might possibly be legit, but it is still causing load on the system and slowing down the internet for everyone. With such an abuse server, ‘bad traffic’ still gets a chance of an answer, but without impacting the rest of the world (too much).

We can similarly add clients to the abuse server:

```
```

To define a pool that should receive only a QPS-limited amount of traffic, do:

```
addAction("com.", QPSPoolAction(10000, "gtld-cluster"))
```

Traffic exceeding the QPS limit will not match that rule, and subsequent rules will apply normally.

Servers can be added to or removed from pools with the Server:addPool() and Server:rmPool() functions respectively:
getServer(4):addPool("abuse")
getServer(4):rmPool("abuse")

17.3 Loadbalancing and Server Policies

dnsdist selects the server (if there are multiple eligible) to send queries to based on the configured policy. Only servers that are marked as ‘up’, either forced so by the administrator or as the result of the last health check, might be selected.

17.3.1 Built-in Policies

leastOutstanding

The default load balancing policy is called leastOutstanding, which means the server with the least queries ‘in the air’ is picked. The exact selection algorithm is:

• pick the server with the least queries ‘in the air’;
• in case of a tie, pick the one with the lowest configured ‘order’;
• in case of a tie, pick the one with the lowest measured latency (over an average on the last 128 queries answered by that server).

firstAvailable

The firstAvailable policy, picks the first available server that has not exceeded its QPS limit, ordered by increasing ‘order’. If all servers are above their QPS limit, a server is selected based on the leastOutstanding policy. For now this is the only policy using the QPS limit.

wrandom

A further policy, wrandom assigns queries randomly, but based on the weight parameter passed to newServer().

For example, if two servers are available, the first one with a weight of 2 and the second one with a weight of 1 (the default), the first one should get two-thirds of the incoming queries and the second one the remaining third.

Since 1.5.0, a bounded-load version is also supported, trying to prevent one server from receiving much more queries than intended, even if the distribution of queries is not perfect. This “weighted random with bounded loads” algorithm is enabled by setting setWeightedBalancingFactor() to a value other than 0, which is the default. This value is the maximum number of outstanding queries that a given server can have at a given time, as a ratio of the total number of outstanding queries for all the active servers in the pool, pondered by the weight of the server.

The algorithm will try to select a server randomly, as is done when no bounded-load is set, but will disqualify all servers that have more outstanding queries than intended times the factor, until a suitable server is found. The higher the factor, the more imbalance between the servers is allowed.

For example, if we have two servers, with respective weights of 1 and 4, we expect the first server to get a fifth of the queries, and the second one 4/5. As the random distribution is not perfect, some server might get more queries than expected. Setting setWeightedBalancingFactor() to 1.1 limits the imbalance between the ratio of outstanding queries actually handled by a server and the expected number, so in this example the first server would not be allowed to handle more than 1.1/5 of all the outstanding queries at a given time.
whashed

whashed is a similar weighted policy, but assigns questions with identical hash to identical servers, allowing for better cache concentration ("sticky queries"). The current hash algorithm is based on the qname of the query.

`setWHashedPertubation(value)`

Set the hash perturbation value to be used in the whashed policy instead of a random one, allowing to have consistent whashed results on different instances.

Since 1.5.0, a bounded-load version is also supported, trying to prevent one server from receiving much more queries than intended, even if the distribution of queries is not perfect. This "weighted hashing with bounded loads" algorithm is enabled by setting `setWeightedBalancingFactor()` to a value other than 0, which is the default. This value is the maximum number of outstanding queries that a given server can have at a given time, as a ratio of the total number of outstanding queries for all the active servers in the pool, pondered by the weight of the server.

The algorithm will try to select a server based on the hash of the qname, as is done when no bounded-load is set, but will disqualify all servers that have more outstanding queries than intended times the factor, until a suitable server is found. The higher the factor, the more imbalance between the servers is allowed.

For example, if we have two servers, with respective weights of 1 and 4, we expect the first server to get a fifth of the queries, and the second one 4/5. If the qname of the queries are not perfectly distributed, some server might get more queries than expected. Setting `setWeightedBalancingFactor()` to 1.1 limits the imbalance between the ratio of outstanding queries actually handled by a server and the expected number, so in this example the first server would not be allowed to handle more than 1.1/5 of all the outstanding queries at a given time.

chashed

chashed is a consistent hashing distribution policy. Identical questions with identical hashes will be distributed to the same servers. But unlike the whashed policy, this distribution will keep consistent over time. Adding or removing servers will only remap a small part of the queries.

Increasing the weight of servers to a value larger than the default is required to get a good distribution of queries. Small values like 100 or 1000 should be enough to get a correct distribution. This is a side-effect of the internal implementation of the consistent hashing algorithm, which assigns as many points on a circle to a server than its weight, and distributes a query to the server who has the closest point on the circle from the hash of the query’s qname. Therefore having very few points, as is the case with the default weight of 1, leads to a poor distribution of queries.

You can also set the hash perturbation value, see `setWHashedPertubation()`. To achieve consistent distribution over `dnsdist` restarts, you will also need to explicitly set the backend’s UUIDs with the `id` option of `newServer()`. You can get the current UUIDs of your backends by calling `showServers()` with the `showUUIDs=true` option.

Since 1.5.0, a bounded-load version is also supported, preventing one server from receiving much more queries than intended, even if the distribution of queries is not perfect. This “consistent hashing with bounded loads” algorithm is enabled by setting `setConsistentHashingBalancingFactor()` to a value other than 0, which is the default. This value is the maximum number of outstanding queries that a given server can have at a given time, as a ratio of the total number of outstanding queries for all the active servers in the pool, pondered by the weight of the server.

The algorithm will try to select a server based on the hash of the qname, as is done when no bounded-load is set, but will disqualify all servers that have more outstanding queries than intended times the factor, until a suitable server is found. The higher the factor, the more imbalance between the servers is allowed.

For example, if we have two servers, with respective weights of 1 and 4, we expect the first server to get a fifth of the queries, and the second one 4/5. If the qname of the queries are not perfectly distributed, some server might get more queries than expected. Setting `setConsistentHashingBalancingFactor()` to 1.1 limits the imbalance between the ratio of outstanding queries actually handled by a server and the expected number, so in this example the first server would not be allowed to handle more than 1.1/5 of all the outstanding queries at a given time.
The last available policy is roundrobin, which indiscriminately sends each query to the next server that is up. If all servers are down, the policy will still select one server by default. Setting setRoundRobinFailOnNoServer() to true will change this behavior.

### 17.3.2 Lua server policies

If you don’t like the default policies you can create your own, like this for example:

```lua
counter=0
function luaroundrobin(servers, dq)
    counter=counter+1
    return servers[1+(counter % #servers)]
end
setServerPolicyLua("luaroundrobin", luaroundrobin)
```

Incidentally, this is similar to setting: setServerPolicy(roundrobin) which uses the C++ based roundrobin policy.

Or:

```lua
newServer("192.168.1.2")
newServer({address="8.8.4.4", pool="numbered"})

function splitSetup(servers, dq)
    if(string.match(dq.qname:toString(), "%d"))
        print("numbered pool")
        return leastOutstanding.policy(getPoolServers("numbered"), dq)
    else
        print("standard pool")
        return leastOutstanding.policy(servers, dq)
    end
end
setServerPolicyLua("splitsetup", splitSetup)
```

For performance reasons, 1.6.0 introduced per-thread Lua FFI policies that are run in a lock-free per-thread Lua context instead of the global one. This reduces contention between threads at the cost of preventing sharing data between threads for these policies. Since the policy needs to be recompiled in the context of each thread instead of the global one, Lua code that returns a function should be passed to the function as a string instead of directly passing the name of a function:

```lua
setServerPolicyLuaFFIPerThread("luaffiroundrobin", "{local ffi = require("ffi")
local C = ffi.C
local counter = 0
return function(servers_list, dq)
    counter = counter + 1
    return (counter % tonumber(C.dnsdist ffi_servers_list_get_count(servers_list)))
end}")
```

### 17.3.3 ServerPolicy Objects

**class ServerPolicy**

This represents a server policy. The built-in policies are of this type
ServerPolicy.policy \((\text{servers}, dq) \rightarrow \text{Server}\)
Run the policy to receive the server it has selected.

**Parameters**

- **servers** – A list of Server objects
- **dq**(DNSQuestion) – The incoming query

**ServerPolicy.ffiPolicy**
For policies implemented using the Lua FFI interface, the policy function itself.

**ServerPolicy.isFFI**
Whether a Lua-based policy is implemented using the FFI interface.

**ServerPolicy.isLua**
Whether this policy is a native (C++) policy or a Lua-based one.

**ServerPolicy.isPerThread**
Whether a FFI Lua-based policy is executed in a lock-free per-thread context instead of running in the global Lua context.

**ServerPolicy.name**
The name of the policy.

**ServerPolicy.policy**
The policy function itself, except for FFI policies.

Server:toString()
Return a textual representation of the policy.

### 17.3.4 Functions

**newServerPolicy**(name, function) \(\rightarrow\) ServerPolicy
Create a policy object from a Lua function. function must match the prototype for `ServerPolicy.policy()`.

**Parameters**

- **name**(string) – Name of the policy
- **function**(string) – The function to call for this policy

**setConsistentHashingBalancingFactor**(factor)
Set the maximum imbalance between the number of outstanding queries intended for a given server, based on its weight, and the actual number, when using the chashed consistent hashing load-balancing policy. Default is 0, which disables the bounded-load algorithm.

**setServerPolicy**(policy)
Set server selection policy to policy.

**Parameters**

- **policy**(ServerPolicy) – The policy to use

**setServerPolicyLua**(name, function)
Set server selection policy to one named name and provided by function.

**Parameters**

- **name**(string) – name for this policy
- **function**(string) – name of the function

**setServerPolicyLuaFFI**(name, function)
New in version 1.5.0.
Set server selection policy to one named name and provided by the FFI function function.

**Parameters**
• name (string) – name for this policy
• function (string) – name of the FFI function

setServerPolicyLuaFFIPerThread (name, code)
New in version 1.6.0.
Set server selection policy to one named name and the Lua FFI function returned by the Lua code passed in code. The resulting policy will be executed in a lock-free per-thread context, instead of running in the global Lua context.

Parameters
• name (string) – name for this policy
• code (string) – Lua FFI code returning the function to execute as a server selection policy

setServFailWhenNoServer (value)
If set, return a ServFail when no servers are available, instead of the default behaviour of dropping the query.

Parameters value (bool) – whether to return a servfail instead of dropping the query

setPoolServerPolicy (policy, pool)
Set the server selection policy for pool to policy.

Parameters
• policy (ServerPolicy) – The policy to apply
• pool (string) – Name of the pool

setPoolServerPolicyLua (name, function, pool)
Set the server selection policy for pool to one named name and provided by function.

Parameters
• name (string) – name for this policy
• function (string) – name of the function
• pool (string) – Name of the pool

setRoundRobinFailOnNoServer (value)
New in version 1.4.0.
By default the roundrobin load-balancing policy will still try to select a backend even if all backends are currently down. Setting this to true will make the policy fail and return that no server is available instead.

Parameters value (bool) – whether to fail when all servers are down

setWeightedBalancingFactor (factor)
Set the maximum imbalance between the number of outstanding queries intended for a given server, based on its weight, and the actual number, when using the whashed or wrandom load-balancing policy. Default is 0, which disables the bounded-load algorithm.

showPoolServerPolicy (pool)
Print server selection policy for pool.

Parameters pool (string) – The pool to print the policy for
These chapters contain information on the advanced features of dnsdist

18.1 Access Control

dnsdist can be used to front traditional recursive nameservers, these usually come with a way to limit the network ranges that may query it to prevent becoming an open resolver. To be a good internet citizen, dnsdist by default listens on the loopback address (127.0.0.1:53) and limits queries to these loopback, RFC 1918 and other local addresses:

- 127.0.0.0/8
- 10.0.0.0/8
- 100.64.0.0/10
- 169.254.0.0/16
- 192.168.0.0/16
- 172.16.0.0/12
- ::1/128
- fc00::/7
- fe80::/10

The ACL applies to queries received over UDP, TCP, DNS over TLS and DNS over HTTPS.
Further more, dnsdist only listens for queries on the local-loopback interface by default.

18.1.1 Listening on different addresses

To listen on other addresses than just the local addresses, use setLocal() and addLocal().

setLocal() resets the list of current listen addresses to the specified address and addLocal() adds an additional listen address. To listen on 127.0.0.1:5300, 192.0.2.1:53 and UDP-only on [2001:db8::15::47]:53, configure the following:

```plaintext
setLocal('127.0.0.1:5300')
addLocal('192.0.2.1')  -- Port 53 is default is none is specified
addLocal('2001:db8::15::47', false)
```

Listen addresses cannot be modified at runtime and must be specified in the configuration file.

As dnsdist is IPv4 and IPv6 agnostic, this means that dnsdist internally does not know the difference. So feel free to listen on the magic 0.0.0.0 or :: addresses, dnsdist does the right thing to set the return address of queries, but set your ACL properly.
18.1.2 Modifying the ACL

ACLs can be modified at runtime from the Working with the dnsdist Console. To inspect the currently active ACL, run showACL().

To add a new network range to the existing ACL, use addACL():

```plaintext
addACL('192.0.2.0/25')
addACL('2001:db8::1')  -- No netmask specified, only allow this address
```

To remove a previously added network range from the existing ACL, use rmACL():

```plaintext
rmACL('192.0.2.0/25')
rmA(CL('2001:db8::1')  -- No netmask specified, only remove this address
```

dnsdist also has the setACL() function that accepts a list of netmasks and resets the ACL to that list:

```plaintext
setACL({'192.0.2.0/25', '2001:db8:15::bea/64'})
```

To set the ACL from a file containing a list of netmasks, use setACLFromFile():

```plaintext
setACLFromFile('/etc/dnsdist/query.acl')
```

18.2 Passing the source address to the backend

dnsdist, as a load-balancer, receives the UDP datagrams and terminates the TCP connections with the client. It therefore knows the source IP address and port of that client, as well as the original destination address, port, and protocol. Very often the backend needs to know that information as well, to pass EDNS Client Subnet to an authoritative server, to do GeoIP-based processing or even custom filtering.

There are several ways to pass that information using dnsdist: EDNS Client Subnet, X-Proxied-For and the Proxy Protocol.

18.2.1 Using EDNS Client Subnet

EDNS Client Subnet (ECS) is a standardized EDNS option designed to pass a bit of information about the client from a resolver to authoritative servers. While it was not designed with our use-case in mind, it can be used by dnsdist to send the source IP, but only the source IP, to its backend.

In order to provide the downstream server with the address of the real client, or at least the one talking to dnsdist, the useClientSubnet parameter can be used when creating a new server. This parameter indicates whether an EDNS Client Subnet option should be added to the request.

The default source prefix-length is 24 for IPv4 and 56 for IPv6, meaning that for a query received from 192.0.2.42, the EDNS Client Subnet value sent to the backend will be 192.0.2.0. This can be changed with setECSSourcePrefixV4() and setECSSourcePrefixV6().

If the incoming request already contains an EDNS Client Subnet value, it will not be overridden unless setECSoverride() is set to true.

In addition to the global settings, rules and Lua bindings can alter this behavior per query:

- calling SetDisableECSAction() or setting dq.useECS to false prevents the sending of the ECS option.
- calling SetECSOverrideAction() or setting dq.ecsOverride will override the global setECSoverride() value.
- calling SetECSPrefixLengthAction(v4, v6)() or setting dq.ecsPrefixLength will override the global setECSSourcePrefixV4() and setECSSourcePrefixV6() values.
In effect this means that for the EDNS Client Subnet option to be added to the request, `useClientSubnet` should be set to `true` for the backend used (default to `false`) and ECS should not have been disabled by calling `SetDisableECSAction()` or setting `dq.useECS` to `false` (default to `true`).

Note that any trailing data present in the incoming query is removed when an OPT (or XPF) record has to be inserted.

In addition to the drawback that it can only pass the source IP address, and the fact that it needs to override any existing ECS option, adding that option requires parsing and editing the query, as well as parsing and editing the response in most cases.

<table>
<thead>
<tr>
<th>Payload</th>
<th>Required processing</th>
</tr>
</thead>
<tbody>

<td>edit the OPT record to add an ECS option</td>
</tr>
<tr>
<td>Query, ECS</td>
<td>edit the OPT record to overwrite the ECS option</td>
</tr>
<tr>
<td>Response, no EDNS</td>
<td>none</td>
</tr>
<tr>
<td>Response, EDNS without ECS</td>
<td>remove the OPT record if needed</td>
</tr>
<tr>
<td>Response, EDNS with ECS</td>
<td>remove or edit the ECS option if needed</td>
</tr>
</tbody>
</table>

### 18.2.2 X-Proxied-For

**Note:** This is a deprecated feature that will be removed in the near future.

The experimental XPF record (from draft-bellis-dnsop-xpf) is an alternative to the use of EDNS Client Subnet which has the advantages of preserving any existing EDNS Client Subnet value sent by the client, and of passing along the original destination address, as well as the initial source and destination ports.

In order to provide the downstream server with the address of the real client, or at least the one talking to dnsdist, the `addXPF` parameter can be used when creating a new server. This parameter indicates whether an XPF record shall be added to the query. Since that record is experimental, there is currently no option code assigned to it, and therefore one needs to be specified as an argument to the `addXPF` parameter.

If the incoming request already contains a XPF record, it will not be overwritten. Instead a new one will be added to the query and the existing one will be preserved. That might be an issue by allowing clients to spoof their source address by adding a forged XPF record to their query. That can be prevented by using a rule to drop incoming queries containing a XPF record (in that example the 65280 option code has been assigned to XPF):

```plaintext
addAction(RecordsTypeCountRule(DNSSection.Additional, 65280, 1, 65535), DropAction())
```

### 18.2.3 Proxy Protocol

The Proxy Protocol has been designed by the HAProxy folks for HTTP over TCP, but is generic enough to be used in other places, and is a de-facto standard with implementations in nginx and postfix, for example. It works by pre-pending a small header at the very beginning of a UDP datagram or TCP connection, which holds the initial source and destination addresses and ports, and can also contain several custom values in a Type-Length-Value format. More information about the Proxy Protocol can be found at [https://www.haproxy.org/download/2.2/doc/proxy-protocol.txt](https://www.haproxy.org/download/2.2/doc/proxy-protocol.txt)

In order to use it in dnsdist, the `useProxyProtocol` parameter can be used when creating a new server. This parameter indicates whether a Proxy Protocol version 2 (binary) header should be prepended to the query before forwarding it to the backend, over UDP or TCP. Such a Proxy Protocol header can also be passed from the client to dnsdist, using `setProxyProtocolACL()` to specify which clients to accept it from. Note that a proxy protocol payload will be required from these clients, regular DNS queries will no longer be accepted if they are not preceded by a proxy protocol payload.
If \texttt{setProxyProtocolApplyACLToProxiedClients()} is set (default is false), the general ACL will be applied to the source IP address as seen by dnsdist first, but also to the source IP address provided in the Proxy Protocol header.

Custom values can be added to the header via \texttt{DNSQuestion:addProxyProtocolValue()}, \texttt{DNSQuestion:setProxyProtocolValues()}, \texttt{SetAdditionalProxyProtocolValueAction()} and \texttt{SetProxyProtocolValuesAction()}. Be careful that Proxy Protocol values are sent once at the beginning of the TCP connection for TCP and DoT queries. That means that values received on an incoming TCP connection will be inherited by subsequent queries received over the same incoming TCP connection, if any, but values set to a query will not be inherited by subsequent queries. Please also note that the maximum size of a Proxy Protocol header dnsdist is willing to accept is 512 bytes by default, although it can be set via \texttt{setProxyProtocolMaximumPayloadSize()}.

dnsdist 1.5.0 only supports outgoing Proxy Protocol. Support for parsing incoming Proxy Protocol headers has been implemented in 1.6.0, except for DoH where it does not make sense anyway, since HTTP headers already provide a mechanism for that.

Both the PowerDNS Authoritative Server and the Recursor can parse PROXYv2 headers, if configured to do so with their \texttt{proxy-protocol-from} setting.

### 18.2.4 Influence on caching

When dnsdist’s packet cache is in use, it is important to note that the cache lookup is done \texttt{after} adding ECS, because it prevents serving the same response to clients from different subnets when ECS is passed to an authoritative server doing GeoIP, or to a backend doing custom filtering. However that means that passing a narrow ECS source will effectively kill dnsdist’s cache ratio, since a given answer will only be a cache hit for clients in the same ECS subnet. Therefore, unless a broad ECS source (greater than 24, for example) is used, it’s better to disable caching.

One exception to that rule is the zero-scope feature, which allows dnsdist to detect that a response sent by the backend has a 0-scope ECS value, indicating that the answer is not ECS-specific and can be used for all clients. dnsdist will then store the answer in its packet cache using the initial query, before ECS has been added. For that feature to work, dnsdist will look up twice into the packet cache when a query arrives, first without and then with ECS. That way, when most of the responses sent by a backend are not ECS-specific and can be served to all clients, dnsdist will still be able to have a great cache-hit ratio for non ECS-specific entries.

That feature is enabled by setting \texttt{disableZeroScope=false} on \texttt{newServer()} (default) and \texttt{parseECS=true} on \texttt{newPacketCache()} (not the default).

Things are different for XPF and the proxy protocol, because dnsdist then does the cache lookup \texttt{before} adding the payload. It means that caching can still be enabled as long as the response is not source-dependent, but should be disabled otherwise.

<table>

<td>Yes</td>
<td>Depends on the backend</td>
</tr>
</tbody>
</table>

### 18.3 TeeAction: copy the DNS traffic stream

This action sends off a copy of a UDP query to another server, and keeps statistics on the responses received.

Sample use:

```
> addAction(AllRule(), TeeAction("192.0.2.54"))
> getAction(0):printStats()
refuseds 0
nxdomains 0
```

(continues on next page)
It is also possible to share a `TeeAction()` between several rules. Statistics will be combined in that case.

**18.4 Lua actions in rules**

While we can pass every packet through the `blockFilter()` functions, it is also possible to configure `dnsdist` to only hand off some packets for Lua inspection. If you think Lua is too slow for your query load, or if you are doing heavy processing in Lua, this may make sense.

To select specific packets for Lua attention, use `addAction()` with `LuaAction()`, or `addResponseAction()` with `LuaResponseAction()`.

A sample configuration could look like this:

```lua
function luarule(dq)
    if (dq.qtype==35) -- NAPTR
        then
        return DNSAction.Pool, "abuse" -- send to abuse pool
    else
        return DNSAction.None, "" -- no action
    end
end
addAction(AllRule(), LuaAction(luarule))
```

**18.5 Runtime-modifiable IP address sets**

From within `maintenance()` or other places, we may find that certain IP addresses must be treated differently for a certain time.

This may be used to temporarily shunt traffic to another pool for example.

`TimedIPSetRule()` creates an object to which native IP addresses can be added in `ComboAddress` form.

`TimedIPSetRule() → TimedIPSetRule`

*Returns a `TimedIPSetRule`.*

**class TimedIPSetRule**

Can be used to handle IP addresses differently for a certain time.

`:add(address, seconds)`

Add an IP address to the set for the next `seconds` seconds.

**Parameters**

- `address` (`ComboAddress`) – The address to add
  - `seconds` (`int`) – Time to keep the address in the Rule

`:cleanup()`

Purge the set from expired IP addresses
dnsdist

:clear()
Clear the entire set
:slice()
Convert the TimedIPSetRule into a DNSRule that can be passed to addAction()

A working example:

```lua
local tisrElGoog = TimedIPSetRule()
local tisrRest = TimedIPSetRule()
addAction(tisrElGoog:slice(), PoolAction("elgoog"))
addAction(tisrRest:slice(), PoolAction(""))

local elgoogPeople = newNMG()
elgoogPeople:addMask("192.168.5.0/28")

function pickPool(dq)
  if elgoogPeople:match(dq.remoteaddr) then
    print("Lua caught query for a googlePerson")
    tisrElGoog:add(dq.remoteaddr, 10)
    return DNSAction.Pool, "elgoog"
  else
    print("Lua caught query for restPerson")
    tisrRest:add(dq.remoteaddr, 60)
    return DNSAction.None, ""
  end
end

addAction(AllRule(), LuaAction(pickPool))
```

18.6 Rules for traffic exceeding QPS limits

Traffic that exceeds a QPS limit, in total or per IP (subnet) can be matched by the MaxQPSIPRule()-rule. For example:

```lua
addAction(MaxQPSIPRule(5, 32, 48), DelayAction(100))
```

This measures traffic per IPv4 address and per /48 of IPv6, and if UDP traffic for such an address (range) exceeds 5 qps, it gets delayed by 100ms.

As another example:

```lua
addAction(MaxQPSIPRule(5), SetNoRecurseAction())
```

This strips the Recursion Desired (RD) bit from any traffic per IPv4 or IPv6 /64 that exceeds 5 qps. This means any those traffic bins is allowed to make a recursor do ‘work’ for only 5 qps.

If this is not enough, try:

```lua
addAction(MaxQPSIPRule(5), DropAction())
```

This will respectively drop traffic exceeding that 5 QPS limit per IP or range, or return it with TC=1, forcing clients to fall back to TCP.

To turn this per IP or range limit into a global limit, use NotRule(MaxQPSRule(5000)) instead of MaxQPSIPRule().
18.7 eBPF Socket Filtering

dnsdist can use eBPF socket filtering on recent Linux kernels (4.1+) built with eBPF support (CONFIG_BPF, CONFIG_BPF_SYSCALL, ideally CONFIG_BPF_JIT). It requires dnsdist to have the CAP_SYS_ADMIN capabilities at startup, or the more restrictive CAP_BPF one since Linux 5.8.

**Note:** To retain the required capability, CAP_SYS_ADMIN or CAP_BPF depending on the Linux kernel version, it is necessary to call `addCapabilitiesToRetain()` during startup, as dnsdist drops capabilities after startup.

**Note:** eBPF can be used by unprivileged users lacking the CAP_SYS_ADMIN (or CAP_BPF) capability on some kernels, depending on the value of the kernel.unprivileged_bpf_disabled sysctl. Since 5.15 that kernel build setting BPF_UNPRIV_DEFAULT_OFF is enabled by default, which prevents unprivileged users from using eBPF.

**Note:** AppArmor users might need to update their policy to allow dnsdist to keep the CAP_SYS_ADMIN (or CAP_BPF) capability. Adding a `capability bpf`, (for CAP_BPF) line to the policy file is usually enough.

**Note:** In addition to keeping the correct capability, large maps might require an increase of RLIMIT_MEMLOCK, as mentioned below.

This feature allows dnsdist to ask the kernel to discard incoming packets in kernel-space instead of them being copied to userspace just to be dropped, thus being a lot of faster. The current implementation supports dropping UDP and TCP queries based on the source IP and UDP datagrams on exact DNS names. We have not been able to implement suffix matching yet, due to a limit on the maximum number of EBPF instructions.

The following figure show the CPU usage of dropping around 20k qps of traffic, first in userspace (34 to 36) then in kernel space with eBPF (37 to 39). The spikes are caused because the drops are triggered by dynamic rules, so the first spike is the abuse traffic before a rule is automatically inserted, and the second spike is because the rule expires automatically after 60s before being inserted again.

The BPF filter can be used to block incoming queries manually:

```bash
> bpf = newBPFFilter({ipv4MaxItems=1024, ipv6MaxItems=1024, qnamesMaxItems=1024})
> bpf:attachToAllBinds()
> bpf:block(newCA("2001:DB8::42"))
> bpf:blockQName(newDNSName("evildomain.com"), 255)
```

(continues on next page)
The `BPFFilter:blockQName()` method can be used to block queries based on the exact qname supplied, in a case-insensitive way, and an optional qtype. Using the 255 (ANY) qtype will block all queries for the qname, regardless of the qtype. Contrary to source address filtering, qname filtering only works over UDP. TCP qname filtering can be done the usual way:

```plaintext
addAction(AndRule({TCPRule(true), makeRule("evildomain.com")}), DropAction())
```

The `BPFFilter:attachToAllBinds()` method attaches the filter to every existing bind at runtime. It cannot use at configuration time. The `setDefaultBPFFilter()` should be used at configuration time.

The `BPFFilter:attachToAllBinds()` automatically attached to every bind:

```plaintext
bpf = newBPFFilter({ipv4MaxItems=1024, ipv6MaxItems=1024, qnamesMaxItems=1024})
setDefaultBPFFilter(bpf)
```

Finally, it’s also possible to attach it to specific binds at runtime:

```plaintext
> bpf = newBPFFilter({ipv4MaxItems=1024, ipv6MaxItems=1024, qnamesMaxItems=1024})
> showBinds()
<table>
<thead>
<tr>
<th>#</th>
<th>Address</th>
<th>Protocol</th>
<th>Queries</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>::1:53</td>
<td>UDP</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>::1:53</td>
<td>TCP</td>
<td>0</td>
</tr>
</tbody>
</table>
> bd = getBind(0)
> bd:attachFilter(bpf)
```

`dnsdist` also supports adding dynamic, expiring blocks to a BPF filter:

```plaintext
bpf = newBPFFilter({ipv4MaxItems=1024, ipv6MaxItems=1024, qnamesMaxItems=1024})
setDefaultBPFFilter(bpf)
local dbr = dynBlockRulesGroup()
dbr:setQueryRate(20, 10, "Exceeded query rate", 60)
function maintenance()
    dbr:apply()
end
```

This will dynamically block all hosts that exceeded 20 queries/s as measured over the past 10 seconds, and the dynamic block will last for 60 seconds.

Since 1.6.0, the default BPF filter set via `setDefaultBPFFilter()` will automatically get used when a “drop” dynamic block is inserted via a `DynBlockRulesGroup`, which provides a better way to combine dynamic blocks with eBPF filtering. Before that, it was possible to use the `addBPFFilterDynBlocks()` method instead:

```plaintext
-- this is a legacy method, please see above for DNSdist >= 1.6.0
bpf = newBPFFilter({ipv4MaxItems=1024, ipv6MaxItems=1024, qnamesMaxItems=1024})
setDefaultBPFFilter(bpf)
dbpf = newDynBPFFilter(bpf)
function maintenance()
    addBPFFilterDynBlocks(exceedQRate(20, 10), dbpf, 60)
    dbpf:purgeExpired()
end
```

The dynamic eBPF blocks and the number of queries they blocked can be seen in the web interface and retrieved from the API. Note however that eBPF dynamic objects need to be registered before they appear in the web interface.
They can be unregistered at a later point using the `unregisterDynBPFFilter()` function. Since 1.8.2, the metrics for the BPF filter registered via `setDefaultBPFFilter()` are exported as well.

### 18.7.1 Requirements

In addition to the capabilities explained above, that feature might require an increase of the memory limit associated to a socket, via the sysctl setting `net.core.optmem_max`. When attaching an eBPF program to a socket, the size of the program is checked against this limit, and the default value might not be enough.

Large map sizes might also require an increase of `RLIMIT_MEMLOCK`, which can be done by adding `LimitMEMLOCK=limit` in the systemd unit file, where limit is specified using byte as unit. It can also be done manually for testing purposes, in a non-permanent way, by using `ulimit -l`.

To change the default hard limit on `RLIMIT_MEMLOCK` add the following line to `/etc/security/limits.conf` for the user, specifying a limit in units of 1k, for example:

```bash
$USER hard memlock 1024
```

### 18.7.2 External program, maps and XDP filtering

Since 1.7.0 dnsdist has the ability to expose its eBPF map to external programs. That feature makes it possible to populate the client IP addresses and qnames maps from dnsdist, usually using the dynamic block mechanism, and to act on the content of these maps from an external program, including a XDP one. For example, to instruct dnsdist to create under the `/sys/fs/bpf` mount point of type `bpf` three maps of maximum 1024 entries each, respectively pinned to `/sys/fs/bpf/dnsdist/addr-v4`, `/sys/fs/bpf/dnsdist/addr-v6`, `/sys/fs/bpf/dnsdist/qnames` for IPv4 addresses, IPv6 ones, and qnames:

```python
bpf = newBPFFilter({maxItems=1024, pinnedPath='/sys/fs/bpf/dnsdist/addr-v4'},
                  {maxItems=1024, pinnedPath='/sys/fs/bpf/dnsdist/addr-v6'},
                  {maxItems=1024, pinnedPath='/sys/fs/bpf/dnsdist/qnames'},
                  True)
```

**Note:** By default only root can write into a bpf mount point, but it is possible to create a `dnsdist/` sub-directory with `mkdir` and to make it owned by the `dnsdist` user with `chown`.

The last parameter to `newBPFFilter()` is set to `true` to indicate to dnsdist not to load its internal eBPF socket filter program, which is not needed since packets will be intercepted by an external program and would at best duplicate the work done by the other program. It also tell dnsdist to use a slightly different format for the eBPF maps:

- IPv4 and IPv6 maps still use the address as key, but the value contains an action field in addition to the ‘matched’ counter, to allow for more actions than just dropping the packet
- the qname map now uses the qname and qtype as key, instead of using only the qname, and the value contains the action and counter fields described above instead of having a counter and the qtype

The first, legacy format is still used because of the limitations of eBPF socket filter programs on older kernels, and the number of instructions in particular, that prevented us from using the qname and qtype as key. We will likely switch to the newer format by default once Linux distributions stop shipping these older kernels. XDP programs require newer kernel versions anyway and have thus fewer limitations.

XDP programs are more powerful than eBPF socket filtering ones as they are not limited to accepting or denying a packet, but can immediately craft and send an answer. They are also executed a bit earlier in the kernel networking path so can provide better performance.

A sample program using the maps populated by dnsdist in an external XDP program can be found in the `contrib` directory of our git repository. That program supports answering with a TC=1 response instead of simply dropping the packet.
18.8 Performance Tuning

First, a few words about dnsdist architecture:

- Each local bind has its own thread listening for incoming UDP queries
- and its own thread listening for incoming TCP connections, dispatching them right away to a pool of TCP worker threads
- Each backend has its own thread listening for UDP responses, including the ones triggered by DoH queries, if any
- A maintenance thread calls the maintenance() Lua function every second if any, and is responsible for cleaning the cache
- A health check thread checks the backends availability
- A control thread handles console connections, plus one thread per connection
- A carbon thread exports statistics to carbon servers if needed
- One or more webserver threads handle queries to the internal webserver, plus one thread per HTTP connection
- A SNMP thread handles SNMP operations, when enabled.

18.8.1 UDP and incoming DNS over HTTPS

dnsdist design choices mean that the processing of UDP and DNS over HTTPS queries is done by only one thread per local bind (per addLocal(), addDNSCryptLocal() and addDOHLocal() directive).

This is great to keep lock contention to a low level, but might not be optimal for setups using a lot of processing power, caused for example by a large number of complicated rules. To be able to use more CPU cores for UDP queries processing, it is possible to use the reusePort parameter of the addLocal() and setLocal() directives to be able to add several identical local binds to dnsdist:

```
addLocal("192.0.2.1:53", {reusePort=true})
addLocal("192.0.2.1:53", {reusePort=true})
addLocal("192.0.2.1:53", {reusePort=true})
addLocal("192.0.2.1:53", {reusePort=true})
```

dnsdist will then add four identical local binds as if they were different IPs or ports, start four threads to handle incoming queries and let the kernel load balance those randomly to the threads, thus using four CPU cores for rules processing. Note that this require SO_REUSEPORT support in the underlying operating system (added for example in Linux 3.9). Please also be aware that doing so will increase lock contention and might not therefore scale linearly, as discussed below.
Another possibility is to use the reuseport option to run several dnsdist processes in parallel on the same host, thus avoiding the lock contention issue at the cost of having to deal with the fact that the different processes will not share informations, like statistics or DDoS offenders.

The UDP threads handling the responses from the backends do not use a lot of CPU, but if needed it is also possible to add the same backend several times to the dnsdist configuration to distribute the load over several responder threads:

```plaintext
newServer({address="192.0.2.127:53", name="Backend1"})
newServer({address="192.0.2.127:53", name="Backend2"})
newServer({address="192.0.2.127:53", name="Backend3"})
newServer({address="192.0.2.127:53", name="Backend4"})
```

When dispatching UDP queries to backend servers, dnsdist keeps track of at most \( n \) outstanding queries for each backend. This number \( n \) can be tuned by the `setMaxUDPOutstanding()` directive, defaulting to 65535 which is the maximum value.

Changed in version 1.4.0: The default was 10240 before 1.4.0

Large installations running dnsdist before 1.4.0 are advised to increase the default value at the cost of a slightly increased memory usage.

Looking at `udp-in-errors` in `dumpStats()` will reveal whether the system is dropping UDP datagrams because dnsdist does not pick them up fast enough. In that case it might be good to add more `addLocal()` directives. In the same way, if the number of Drops in `showServers()` increase fast enough, it might mean that the backend is overloaded but also that the UDP received thread is. In that case adding more `newServer()`

Using a single connected UDP socket to contact a backend, and thus a single (source address, source port, destination address, destination port) tuple, might not play well with some load-balancing mechanisms present in front of the backend. Linux's `reuseport`, for example, does not balance the incoming datagrams to several threads in that case. That can be worked around by using the `sockets` option of the `newServer()` directive to open several sockets instead of one. You may want to set that number to a value somewhat higher than the number of worker threads configured in the backend. dnsdist will then select a socket using round-robin to forward a query to the backend, and use event multiplexing on the receiving side.

Note that, since 1.7, dnsdist supports marking a backend as “TCP only”, as well as enabling DNS over TLS communication between dnsdist and that backend. That leads to a different model where UDP queries are instead passed to a TCP worker:

```
For DNS over HTTPS, every `addDOHLocal()` directive adds a new thread dealing with incoming connections, so it might be useful to add more than one directive, as indicated above.

When dealing with a large traffic load, it might happen that the internal pipe used to pass queries between the threads handling the incoming connections and the one getting a response from the backend become full too quickly, degrading performance and causing timeouts. This can be prevented by increasing the size of the internal pipe buffer, via the `internalPipeBufferSize` option of `addDOHLocal()`. Setting a value of 1048576 is known to yield good results on Linux.

18.8. Performance Tuning 121
18.8.2 Outgoing DoH

Starting with 1.7.0, dnsdist supports communicating with the backend using DNS over HTTPS. The incoming queries, after the processing of rules if any, are passed to one of the DoH workers over a pipe. The DoH worker handles the communication with the backend, retrieves the response, and either responds directly to the client (queries coming over UDP) or pass it back over a pipe to the initial thread (queries coming over TCP, DoT or DoH). The number of outgoing DoH worker threads can be configured using `setOutgoingDoHWorkerThreads()`.

18.8.3 TCP and DNS over TLS

Before 1.4.0, a TCP thread could only handle a single incoming connection at a time. Starting with 1.4.0 the handling of TCP connections is now event-based, so a single TCP worker can handle a large number of TCP incoming connections simultaneously. Note that before 1.6.0 the TCP worker threads were created at runtime, adding a new thread when the existing ones seemed to struggle with the load, until the maximum number of threads had been reached. Starting with 1.6.0 the configured number of worker threads are immediately created at startup.

The maximum number of threads in the TCP / DNS over TLS pool is controlled by the
The `setMaxTCPClientThreads()` directive, and defaults to 10. This number can be increased to handle a large number of simultaneous TCP/DNS over TLS connections.

If all the TCP threads are busy, new TCP connections are queued while they wait to be picked up. The maximum number of queued connections can be configured with `setMaxTCPQueuedConnections()` and defaults to 1000 (10000 on Linux since 1.6.0). Note that the size of the internal pipe used to distribute queries might need to be increased as well, using `setTCPInternalPipeBufferSize()`. Any value larger than 0 will cause new connections to be dropped if there are already too many queued.

By default, every TCP worker thread has its own queue, and the incoming TCP connections are dispatched to TCP workers on a round-robin basis. This might cause issues if some connections are taking a very long time, since incoming ones will be waiting until the TCP worker they have been assigned to has finished handling its current query, while other TCP workers might be available.

The experimental `setTCPUseSinglePipe()` directive can be used so that all the incoming TCP connections are put into a single queue and handled by the first TCP worker available. This used to be useful before 1.4.0 because a single connection could block a TCP worker, but the “one pipe per TCP worker” is preferable now that workers can handle multiple connections to prevent waking up all idle workers when a new connection arrives. This option will be removed in 1.7.0.

One of the first starting point when investigating TCP or DNS over TLS issues is to look at the `showTCPStats()` command. It provides a lot of metrics about the current and passed connections, and why they were closed.

If the number of queued connections (“Queued” in `showTCPStats()`) reaches the maximum number of queued connections (“Max Queued” in `showTCPStats()`) then there is clearly a problem with TCP workers not picking up new connections quickly enough. It might be a good idea to increase the number of TCP workers.

A different possibility is that there is not enough threads accepting new connections and distributing them to worker threads. Looking at whether the `listenOverflows` metric in `dumpStats()` increase over time will tell if we are losing TCP connections because the queue is full. In that case, since a single `addLocal()` or `addTLSLocal()` directive results in only one acceptor thread, it might useful to add more of these.

For incoming and outgoing DNS over TLS support, the choice of the TLS provider (OpenSSL and GnuTLS are both supported) might yield very different results depending on the exact architecture.

Since 1.8.0, incoming DNS over TLS might also benefit from experimental support for TLS acceleration engines, like Intel QAT. See `loadTLSEngine()`, and the `tlsAsyncMode` parameter of `addTLSLocal()` for more information.

Incoming and outgoing DNS over TLS, as well as outgoing DNS over HTTPS, might benefit from experimental support kernel-accelerated TLS on Linux, when supported by the kernel and OpenSSL. See the `ktls` options on
addTLSLocal() and newServer() for more information. Kernel support for kTLS might be verified by looking at the counters in /proc/net/tls_stat. Note that:

- supported ciphers depend on the exact kernel version used. TLS_AES_128_GCM_SHA256 might be a good option for testing purpose since it was supported pretty early
- as of OpenSSL 3.0.7, kTLS can only be used for sending TLS 1.3 packets, not receiving them. Both sending and receiving packets should be working for TLS 1.2.

### 18.8.4 TLS performance

For DNS over HTTPS and DNS over TLS, in addition to the advice above we suggest reading the TLS Sessions Management page to learn how to improve TLS session resumption ratio, which has a huge impact on CPU usage and latency.

### 18.8.5 Rules and Lua

Most of the query processing is done in C++ for maximum performance, but some operations are executed in Lua for maximum flexibility:

- Rules added by LuaAction(), LuaResponseAction(), LuaFFIACTION() or LuaFFIResponseAction()
- Server selection policies defined via setServerPolicyLua(), setServerPolicyLuaFFI(), setServerPolicyLuaFFIPerThread() or newServerPolicy()

While Lua is fast, its use should be restricted to the strict necessary in order to achieve maximum performance, it might be worth considering using LuaJIT instead of Lua. When Lua inspection is needed, the best course of action is to restrict the queries sent to Lua inspection by using addLuaAction() with a selector.

<table>
<thead>
<tr>
<th>Type</th>
<th>Performance</th>
<th>Locking</th>
</tr>
</thead>
<tbody>
<tr>
<td>C++ rule</td>
<td>fast</td>
<td>none</td>
</tr>
<tr>
<td>Lua rule</td>
<td>slow</td>
<td>global Lua lock</td>
</tr>
<tr>
<td>Lua FFI rule</td>

<td>global Lua lock</td>
</tr>
<tr>
<td>Lua FFI LB policy</td>
<td>fast</td>
<td>global Lua lock</td>
</tr>
</tbody>
</table>

### 18.8.6 Lock contention and sharding

Adding more threads makes it possible to use more CPU cores to deal with the load, but at the cost of possibly increasing lock contention between threads. This is especially true for Lua-intensive setups, because Lua processing in dnsdist is serialized by a unique lock for all threads, as seen above.

For other components, like the packet cache and the in-memory ring buffers, it is possible to reduce the amount of contention by using sharding. Sharding divides the memory into several pieces, every one of these having its own separate lock, reducing the amount of times two threads or more will need to access the same data.

Sharding was disabled by default before 1.6.0 and could be enabled via the numberOfShards option to newPacketCache() and setRingBuffersSize(). It might still make sense to increment the number of shards when dealing with a lot of threads.

### 18.8.7 Memory usage

The main sources of memory usage in DNSDist are:
• packet caches, when enabled
• the number of outstanding UDP queries per backend, configured with `setMaxUDPOutstanding()` (see above)
• the number of entries in the ring-buffers, configured with `setRingBuffersSize()`
• the number of short-lived dynamic block entries
• the number of user-defined rules and actions
• the number of TCP, DoT and DoH connections

Memory usage per connection for connected protocols:

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Memory usage per connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6 kB</td>
</tr>
<tr>
<td>DoT (GnuTLS)</td>

</tr>
<tr>
<td>DoH (http)</td>
<td>2 kB</td>
</tr>
<tr>
<td>DoH</td>
<td>48 kB</td>
</tr>
<tr>
<td>DoH (w/ releaseBuffers)</td>
<td>15 kB</td>
</tr>
</tbody>
</table>

### 18.9 SNMP support

dnsdist supports exporting statistics and sending traps over SNMP when compiled with Net SNMP support, acting as an AgentX subagent. SNMP support is enabled via the `snmpAgent()` directive.

By default, the only traps sent when Traps are enabled, are backend status change notifications. But custom traps can also be sent:

• from Lua, with `sendCustomTrap()` and `DNSQuestion:sendTrap()`

• For selected queries and responses, using `SNMPTrapAction()` and `SNMPTrapResponseAction()`

Net SNMP snmpd doesn’t accept subagent connections by default, so to use the SNMP features of dnsdist the following line should be added to the `snmpd.conf` configuration file:

```plaintext
master agentx
```

In addition to that, the permissions on the resulting socket might need to be adjusted so that the `dnsdist` user can write to it. This can be done with the following lines in `snmpd.conf` (assuming `dnsdist` is running as `dnsdist:dnsdist`):

```plaintext
agentxperms 0700 0700 dnsdist dnsdist
```

In order to allow the retrieval of statistics via SNMP, `snmpd`’s access control has to configured. A very simple SNMPv2c setup only needs the configuration of a read-only community in `snmpd.conf`:

```plaintext
rocommunity dnsdist42
```

`snmpd` also supports more secure SNMPv3 setup, using for example the `createUser` and `rouser` directives:

```plaintext
createUser myuser SHA "my auth key" AES "my enc key"
createUser myuser
```

`snmpd` can be instructed to send SNMPv2 traps to a remote SNMP trap receiver by adding the following directive to the `snmpd.conf` configuration file:

```plaintext
trap2sink 192.0.2.1
```
The description of `dnsdist`'s SNMP MIB is as follows:

```plaintext

(continues on next page)
18.10 AXFR, IXFR and NOTIFY

18.10.1 In front of primaries

When `dnsdist` is deployed in front of a primary authoritative server, it might receive AXFR or IXFR queries destined to this primary. There are two issues that can arise in this kind of setup:

- If the primary is part of a pool of servers, the first SOA query can be directed by `dnsdist` to a different server than the following AXFR/IXFR one, which might fail if the servers are not perfectly synchronised.
- If the primary only allows AXFR/IXFR based on the source address of the requestor, it might be confused by the fact that the source address will be the one from the `dnsdist` server.

The first issue can be solved by routing SOA, AXFR and IXFR requests explicitly to the primary:

```plaintext
newServer({address="192.168.1.2", name="primary", pool={"primary", "otherpool"}})
addAction(OrRule({QTypeRule(DNSQType.SOA), QTypeRule(DNSQType.AXFR), QTypeRule(DNSQType.IXFR)}), PoolAction("primary"))
```

The second one might require allowing AXFR/IXFR from the `dnsdist` source address and moving the source address check to `dnsdist`'s side:

```plaintext
addAction(AndRule({OrRule({QTypeRule(DNSQType.AXFR), QTypeRule(DNSQType.IXFR)}), NotRule(makeRule("192.168.1.0/24"))}), RCodeAction(DNSRCode.REFUSED))
```

Changed in version 1.4.0: Before 1.4.0, the QTypes were in the `dnsdist` namespace. Use `dnsdist.AXFR` and `dnsdist.IXFR` in these versions. Before 1.4.0, the RCodes were in the `dnsdist` namespace. Use `dnsdist.REFUSED` in these versions.

A different way would be to configure `dnsdist` to pass the source IP of the client to the backend. The different options to do that are described in Passing the source address to the backend.

**Warning:** Be wary of `dnsdist` caching the responses to AXFR and IXFR queries and sending these to the wrong clients. This is mitigated by default when the source IP of the client is passed using EDNS Client Subnet, but not when the proxy protocol is used, so disabling caching for these kinds of queries is advised:

```plaintext
-- this rule will not stop the processing, but disable caching for AXFR and IXFR
-- responses
addRule(OrRule({QTypeRule(DNSQType.AXFR), QTypeRule(DNSQType.IXFR)}), SetSkipCacheAction())

-- this rule will route SOA, AXFR and IXFR queries to a specific pool of servers
addRule(OrRule({QTypeRule(DNSQType.SOA), QTypeRule(DNSQType.AXFR), QTypeRule(DNSQType.IXFR)}), PoolAction("primary"))
```
18.10.2 In front of secondaries

When dnsdist is deployed in front of secondaries, however, an issue might arise with NOTIFY queries, because the secondary will receive a notification coming from the dnsdist address, and not the primary’s one. One way to fix this issue is to allow NOTIFY from the dnsdist address on the secondary side (for example with PowerDNS’s trusted-notification-proxy) and move the address check to dnsdist’s side:

```
addAction(AndRule({OpcodeRule(DNSOpcode.Notify), NotRule(makeRule("192.168.1.0/24 -->"))}), RCodeAction(DNSRCode.REFUSED))
```

Changed in version 1.4.0: Before 1.4.0, the RCodes were in the dnsdist namespace. Use dnsdist.REFUSED in these versions.

**Warning:** Be wary of dnsdist caching the responses to NOTIFY queries and sending these to the wrong clients. This is mitigated by default when the source IP of the client is passed using EDNS Client Subnet, but not when the proxy protocol is used, so disabling caching for these kinds of queries is advised:

```
-- this rule will disable the caching of responses for NOTIFY queries
addAction(OpcodeRule(DNSOpcode.Notify), SetSkipCacheAction())
```

18.11 Running multiple instances

Sometimes, it can be advantageous to run multiple instances of dnsdist. Usecases can be:

- Multiple inbound IP addresses with different rule sets
- Taking advantage of more processes, using SO_REUSEPORT

dnsdist supports loading a different configuration file with the `--config` command line switch.

By default, SYSCONFDIR/dnsdist.conf is loaded. SYSCONFDIR is usually /etc or /etc/dnsdist.

18.11.1 Using systemd

On systems with systemd, instance services can be used. To create a dnsdist service named foo, create a dnsdist-foo.conf in SYSCONFDIR, then run `systemctl enable dnsdist@foo.service` and `systemctl start dnsdist@foo.service`.

18.12 Out-of-order

As of 1.6.0, dnsdist supports accepting and processing queries out-of-order as long as the maxInFlight parameter has been set on the frontend, via `addLocal()` and/or `addTLSLocal()`. Note that it is always enabled on DoH frontends. As many as maxInFlight queries will then be read from a TCP connection, processed and forwarded to a backend simultaneously. If there is more queries pending, they will be processed once a response has been sent for one of the already processed queries.

Backends are assumed not to support out-of-order by default, so only one query at a time will be sent over a TCP connection to a backend, meaning that up to maxInFlight connections to a backend might be needed to be able to process all accepted queries. Setting maxInFlight to a value greater than zero on `newServer()` changes that, and up to maxInFlight queries can be sent to a backend simultaneously over the same TCP connection. This of course requires the backend to actually process incoming queries out-of-order, otherwise the latency will be considerably increased, leading to timeouts and degraded service.
As of 1.6.0, only queries from the same incoming client connection will be sent to a server over a single outgoing TCP connection. This will likely change in 1.7.0, once we have had time to check that it has no adverse effects.

Backends for which Proxy Protocol support has been enabled will never be able to reuse the same outgoing TCP connections for different clients, given that the payload indicating the source IP of the client, as seen by dnsdist, is sent once at the beginning of the TCP connection. For the same reason, it might not even be possible to reuse a TCP connection for the same client if any Type-Length-Value data has been sent over that connection.

### 18.13 OCSP Stapling

dnsdist supports OCSP stapling for DNS over HTTPS and DNS over TLS since 1.4.0-rc1. OCSP, Online Certificate Status Protocol (RFC 6960) is a protocol allowing a client to check the expiration status of a certificate from the certification authority (CA) that delivered it. Since the requirement for the client to first retrieve the certificate then do additional steps to gather an OCSP response is not very efficient, and also discloses to the CA which certificate is validated, a mechanism has been designed to allow the server to retrieve the OCSP response from the CA and provide it to the client during the TLS exchange. This mechanism is named the TLS Certificate Status Request extension (RFC 6066), also known as OCSP stapling.

While OCSP stapling is a net win for the client, it means that the server needs to retrieve the OCSP response itself and update it at regular interval, since the OCSP response tends to be short-lived by design.

dnsdist, as for example haproxy, only supports loading the OCSP response from a file, and has no embedded HTTP client to retrieve the OCSP response and refresh it, leaving it to the administrator to regularly retrieve the OCSP response and feed it to dnsdist.

#### 18.13.1 Local PKI

When a local PKI is used to issue the certificate, or for testing purposes, dnsdist provides the `generateOCSPResponse()` function to generate an OCSP response file for a certificate, using the certificate and private key of the certification authority that signed that certificate:

```python
generateOCSPResponse(pathToServerCertificate, pathToCACertificate, pathToCAPrivateKey, outputFile, numberOfDaysOfValidity, numberOfMinutesOfValidity)
```

The resulting file can be directly used with the `addDOHLocal()` or the `addTLSLocal()` functions:

```python
addDOHLocal("127.0.0.1:443", "/path/to/the/server/certificate", "/path/to/the/server/private/key", { "/" }, { ocspResponses="/path/to/generated/ocsp/response" })
addTLSLocal("127.0.0.1:853", "/path/to/the/server/certificate", "/path/to/the/server/private/key", { ocspResponses="/path/to/generated/ocsp/response" })
```

After starting dnsdist, it is possible to update the OCSP response by connecting to the `console`, generating a new OCSP response and calling `reloadAllCertificates()` so that dnsdist reloads the certificates, keys and OCSP responses associated to the DNS over TLS and DNS over HTTPS contexts.

#### 18.13.2 Certificate signed by an external authority

When the certificate has been signed by an external certification authority, the process is a bit more complicated because the OCSP needs to be retrieved from that CA, and there are very few options available to do that at the moment.

One of those options is to use the OpenSSL ocsp command-line tool, although it’s a bit cumbersome to use.

The first step is to retrieve the URL at which the CA provides an OCSP responder. This can be done via the OpenSSL x509 command:
openSSL x509 -noout -ocsp_uri -in /path/to/the/server/certificate

It will output something like “http://ocsp.int-x3.letsencrypt.org”.

Now we can use the OCSP tool to request an OCSP response for this certificate from the CA, provided that we have the certificate of the CA at hand, but it’s usually needed to get a correct chain of certificates anyway:

openSSL ocsp -issuer /path/to/the/ca/certificate -cert /path/to/the/server/certificate -text -url url/we/retrieved/earlier -respout /path/to/write/the/OCSP/response

If everything goes well, this results in an OCSP response for the server certificate being written to /path/to/write/the/OCSP/response. It seems that earlier versions of OpenSSL did not properly handle the URL, and one needed to split the host and path parts of the OCSP URL, and use the -header option of the ocsp command:

openSSL ocsp -issuer /path/to/the/ca/certificate -cert /path/to/the/server/certificate -text -url <path> -header 'Host' <host> -respout /path/to/write/the/OCSP/response

We can now use it directly with the addDOHLocal() or the addTLSLocal() functions:

addDOHLocal("127.0.0.1:443", "/path/to/the/server/certificate", "/path/to/the/server/private/key", 
{ "/"}, 
{ ocspResponses="/path/to/write/the/OCSP/response"})

daddTLSLocal("127.0.0.1:853", "/path/to/the/server/certificate", "/path/to/the/server/private/key", 
{ ocspResponses="/path/to/write/the/OCSP/response"})

Since this response will be only valid for a while, a script needs to be written to retrieve it regularly via cron or any other mechanism. Once the new response has been retrieved, it is possible to tell dnssdist to reload it by connecting to the console and calling reloadAllCertificates() so that it reloads the certificates, keys and OCSP responses associated to the DNS over TLS and DNS over HTTPS contexts.

18.13.3 Testing

Once a valid OCSP response has retrieved and loaded into dnssdist, it is possible to test that everything is working fine using the OpenSSL s_client command:

openSSL s_client -connect <IP:port> -status -servername <SNI name to use> | grep -F 'OCSP Response Status'

should return something like OCSP Response Status: successful (0x0), indicating that the client received a valid OCSP stapling response from the server.

18.14 TLS Sessions Management

18.14.1 TLS sessions

One of the most costly TLS operation is the negotiation of a new session, since both the client and the server need to generate and agree on cryptographic materials. In order to reduce that cost, TLS implements what is called session resumption, where a client opening a new connection to a server can reuse the cryptographic materials negotiated for a previous TLS session.

The following figures show that, with the same number of established incoming connections and queries per second, the ratio of new TLS sessions and resumed sessions has a huge impact on CPU usage:

The necessary information to resume a session can either be kept on the server’s side (sessions) or on the client’s one (tickets). Initially only the server-side approach existed, with two drawbacks:
• the server needs to keep that information at hand, for a client that might never come back;
• sharing that information between several servers is not easy, especially in setups involving anycast or any kind of cluster without strong session affinity.

Nowadays pretty much all clients support the second option, TLS tickets, where the need information is signed and encrypted by the server before being sent to the client, which is responsible for storing it and sending it back when it wants to establish a new session. That reduces the burden of the server while providing the same benefits.

The server uses Session Ticket Encryption Key (STEK) to sign and encrypt the information sent to the client, making it possible to ensure that it is genuine and has not been tampered when the client provides it later. That STEK can be shared by all dnsdist instances in the same cluster, making it possible for any server to resume a session initially generated by a different server.

Knowing the STEK is all the information needed to be able to decrypt a live TLS session, but also a recorded one, so it is very important to keep that key well-protected. It should never be exchanged in clear-text, and ideally should not be written to persistent storage but be kept in a tmpfs with no swap configured. It should also be regularly rotated to preserve TLS’ forward secrecy properties.

18.14.2 Keys management for incoming connections in dnsdist

dnsdist supports both server’s side (sessions) and client’s side (tickets) resumption for incoming connections (client to dnsdist).

Since server-side sessions cannot be shared between several instances, and pretty much all clients support tickets anyway, we do recommend disabling the sessions by passing numberOfStoredSessions=0 to the addDOHLocal() (for DNS over HTTPS) and addTLSLocal() (for DNS over TLS) functions.

By default, dnsdist will generate a new, random STEK at startup for each addTLSLocal() and addDOHLocal() directive, and rotate these STEKs every 12 hours. For each frontend it will keep 5 keys in memory, with only the last one marked as active and used to encrypt new tickets while the remaining ones can still be used to decrypt existing tickets after a rotation. The rotation time and the number of keys to keep in memory can be configured via the numberOfTicketsKeys and ticketsKeysRotationDelay parameters of the addDOHLocal() (for DNS over HTTPS) and addTLSLocal() (for DNS over TLS) functions.

When the automatic rotation mechanism kicks in a new, random key will be added to the list of keys. With the OpenSSL provider, the new key becomes active, so new tickets will be encrypted with this key, and the existing keys become passive and only be used to decrypt existing tickets. With the GnuTLS provider only one key is currently supported so the existing keys are immediately discarded. This automatic rotation can be disabled by setting ticketsKeysRotationDelay to 0.

It is also possible to manually request a STEK rotation using the getDOHFrontend() (DoH) and getTLSContext() (DoT) functions to retrieve the bind object, and calling its rotateTicketsKey method (DOHFrontend:rotateTicketsKey(), TLSContext:rotateTicketsKey()).
The default settings should be fine for most deployments, but generating a random key for every dnsdist instance will not allow resuming the session from a different instance in a cluster. It is also not very useful to have a different key for every addTLSLocal() and addDOHLocal() directive if you are using the same certificate and key, and it would be much better to use the same STEK to improve the session resumption ratio.

In that case it is possible to generate the STEK outside of dnsdist, write it to a file, distribute it to all instances using something like rsync over SSH, and load that file from dnsdist. Please remember that the STEK contains very sensitive data, and should be well-protected from access by unauthorized users. It means that special care should be taken to setting the right permissions on that file. Automatic rotation should then be disabled by setting ticketsKeysRotationDelay to 0.

For the OpenSSL provider (DoT, DoH), generating a random STEK in a file is as simple as getting 80 cryptographically secure random bytes and writing them to a file:

```bash
dd if=/dev/urandom of=/secure-tmp-fs/tickets.key bs=80 count=1
```

For the GnuTLS provider (DoT), the operation is the same but requires only 64 cryptographically secure random bytes:

```bash
dd if=/dev/urandom of=/secure-tmp-fs/tickets.key bs=64 count=1
```

The file can then be loaded at startup by using the ticketKeyFile parameter of the addDOHLocal() (for DNS over HTTPS) and addTLSLocal() (for DNS over TLS) functions.

If the file contains several keys, so for example 240 random bytes, dnsdist will load several STEKs, using the last one for encrypting new tickets and all of them to decrypt existing tickets.

In order to rotate the keys at runtime, it is possible to instruct dnsdist to reload the content of the certificates, keys, and STEKs from the same file used at configuration time, for all DoH and DoH binds, by issuing the reloadAllCertificates() command. It can also be done one bind at a time using the getDOHFrontend() (DoH) and getTLSContext() (DoT) functions to retrieve the bind object, and calling its loadTicketsKeys method (DOHFrontend:loadTicketsKeys(), TLSContext:loadTicketsKeys()).

One possible way of handling manual rotation of the key would be to first:

- generate \( N \) keys in \( N (1..N) \) separate files (for example executing `dd if=/dev/urandom of=/secure-tmp-fs/N.key bs=80 count=1 N` times)
- concatenate the \( N \) files into a single file ("/secure-tmp-fs/STEKs.key") that you pass to dnsdist's ticketKeyFile parameter

Then, when the STEK should be rotated:

- generate one new key file (\( N+1 \))
- delete the first key file (1)
- concatenate the \( 2..N+1 \) files into one ("/secure-tmp-fs/STEKs.key")
- issue reloadAllCertificates() via the dnsdist console, or call loadTicketsKeys('secure-tmp-fs/STEKs.key') for all frontends

This way dnsdist can still decrypt incoming tickets that were encoded via the previous key (the active one is always the one at the end of the file, and we start by removing the one at the beginning of the file).

### 18.14.3 Content of the STEK file

It does not really matter for most operations, but for later reference the format of the OpenSSL STEK is:

- a 16 bytes binary key identifier
- a 32 bytes AES 256 key
- a 32 bytes HMAC SHA-2 256 key
For GnuTLS:
- a 16 bytes binary key identifier
- a 32 bytes AES 256 key
- a 16 bytes HMAC SHA-1 key

18.14.4 Sessions management for outgoing connections
Since 1.7, dnsdist supports securing the connection toward backends using DNS over TLS. For these connections, it keeps a cache of TLS tickets to be able to resume a TLS session quickly. By default that cache contains up to 20 TLS tickets per-backend, is cleaned up every 60s, and TLS tickets expire if they have not been used after 600 seconds. These values can be set at configuration time via:

- `setOutgoingTLSsessionsCacheMaxTicketsPerBackend()`
- `setOutgoingTLSsessionsCacheCleanupDelay()`
- `setOutgoingTLSsessionsCacheMaxTicketValidity()`

18.15 Internal Design
This part of the documentation is intended for developers interested in understanding how the actual code works, and might not be of much interest to regular users.

18.15.1 UDP design

For UDP queries, dnsdist stores the initial ID in a per-backend table called `IDState`. That ID then replaced by one derived from a counter before forwarding the query to the backend, to prevent duplicated IDs sent clients from making it to the backend. When the response is received, dnsdist uses the ID sent by the backend to find the corresponding `IDState` and restores the initial ID, as well as some flags if needed, before sending the response to the client.

That design means that there is a maximum of 65535 in-flight UDP queries per backend. It can actually be even less than that if `setMaxUDPOutstanding()` is set to a lower value, for example to reduce the overall memory usage.

Note that the source address and port used to contact a given backend is set at startup, for performance reasons, and then only changes on reconnect. There might be more than one socket, and thus several ports, if the `sockets` parameter was set to a higher value than 1 on the `newServer()` directive.
Note that, since 1.7, UDP queries can be passed to the backend over TCP if the backend is TCP-only, or configured for DNS over TLS. This is done by passing the incoming query to a TCP worker over a pipe, as was already done for incoming TCP queries.

In that case the response will be sent back, directly by the TCP worker, over UDP, instead of being passed back to the UDP responder thread.

**18.15.2 TCP / DoT design**

For TCP and DoT, a single thread is created for each `addLocal()` and `addTLSLocal()` directive, listening to the incoming TCP sockets, accepting new connections and distributing them over a pipe to the TCP worker threads. These threads handle both the TCP connection with the client and the one with the backend.

**18.15.3 DoH design**

For DoH, two threads are created for each `addDOHLocal()` directive, one handling the TLS and HTTP layers, then passing the queries to the second one over a pipe. The second thread does DNS processing, applying rules and forwarding the query to the backend if needed, over UDP. Note that even if the query does not need to be passed to a backend (cache-hit, self-generated answer), the response will be passed back to the first thread via a pipe, since only that thread deals with the client. If the response comes from a backend, it will be picked up by the regular UDP listener for that backend, the corresponding `IDState` object located, and the response sent to the first thread over a pipe.
Since 1.7, if the UDP response coming from the backend has been truncated (TC bit is set), dnsdist will retry over TCP by passing the query to a TCP worker over a pipe, as was already done for incoming TCP queries. The response will then be passed back to the DoH worker thread over the same pipe that for UDP queries. That also happens if the backend is marked TCP-only, or configured for DNS over TLS, in which case the query is obviously not sent over UDP first but immediately sent to a TCP worker thread.

18.16 Asynchronous processing

Since 1.8.0, dnsdist has the ability to process queries and responses in an asynchronous way, suspending them to continue processing other queries and responses, while we are waiting for an external event to occur.

This is done by calling the `DNSQuestion:suspend()` method on a query or a response to pause it, then later the `getAsynchronousObject()` to retrieve it before resuming via `AsynchronousObject:resume()`.

A timeout must be supplied when pausing a query or a response, to prevent paused objects from piling up, consuming memory. When the timeout expires, the suspended object is automatically retrieved and resumes its processing where it was left.
The following code shows a very simple example that forwards queries and responses to an external component over a unix network socket, and resumes them when it gets an answer from the external component.

```plaintext
local asyncID = 0
local asyncResponderEndpoint = newNetworkEndpoint('/path/to/unix/network/socket/remote/endpoint')
local listener = newNetworkListener()
listener:addUnixListeningEndpoint('/path/to/unix/network/socket/local/endpoint', 0, gotAsyncResponse)
listener:start()

function gotAsyncResponse(endpointID, message, from)
local queryID = tonumber(message)
local asyncObject = getAsynchronousObject(asyncID, queryID)
dq = asyncObject:getDQ()
dq:setTag(filteringTagName, filteringTagValue)
asyncObject:resume()
end

function passQueryToAsyncFilter(dq)
local timeout = 500 -- 500 ms
local buffer = dq:getContent()
local id = dq.dh:getID()
dq:suspend(asyncID, id, timeout)
asyncResponderEndpoint:send(buffer)
return DNSAction.Allow
end

function passResponseToAsyncFilter(dr)
local timeout = 500 -- 500 ms
local buffer = dr:getContent()
local id = dr.dh:getID()
dr:suspend(asyncID, id, timeout)
asyncResponderEndpoint:send(buffer)
return DNSResponseAction.Allow
end
```

(continues on next page)
addAction(AllRule(), LuaAction(passQueryToAsyncFilter))
addCacheHitResponseAction(AllRule(),
LuaResponseAction(passResponseToAsyncFilter))
addResponseAction(AllRule(), LuaResponseAction(passResponseToAsyncFilter))
These chapters contain extensive information on all functions and object available in dnsdist.

### 19.1 Configuration Reference

This page lists all configuration options for dnsdist.

**Note:** When an IPv6 IP:PORT combination is needed, the bracketed syntax from RFC 3986 should be used, e.g. 
“[2001:DB8:14::C0FF:FEE]:5300”.

#### 19.1.1 Functions and Types

Within dnsdist several core object types exist:

- **Server**: generated with `newServer()`, represents a downstream server
- **ComboAddress**: represents an IP address and port
- **DNSName**: represents a domain name
- **Netmask**: represents a netmask
- **NetmaskGroup**: represents a group of netmasks
- **QPSLimiter**: implements a QPS-based filter
- **SuffixMatchNode**: represents a group of domain suffixes for rapid testing of membership
- **DNSHeader**: represents the header of a DNS packet, see `DNSHeader (dh) object`
- **ClientState**: sometimes also called Bind or Frontend, represents the addresses and ports dnsdist is listening on

The existence of most of these objects can mostly be ignored, unless you plan to write your own hooks and policies, but it helps to understand an expressions like:

```bash
getServer(0).order=12  -- set order of server 0 to 12
getServer(0):addPool("abuse")  -- add this server to the abuse pool
```

The . means `order` is a data member, while the : means `addPool` is a member function.

#### 19.1.2 Global configuration

`addCapabilitiesToRetain (capabilities)`

New in version 1.7.0.
Accept a Linux capability as a string, or a list of these, to retain after startup so that privileged operations can still be performed at runtime. Keeping CAP_BPF on kernel 5.8+ for example allows loading eBPF programs and altering eBPF maps at runtime even if the kernel.unprivileged_bpf_disabled sysctl is set. Note that this does not grant the capabilities to the process, doing so might be done by running it as root which we don’t advise, or by adding capabilities via the systemd unit file, for example. Please also be aware that switching to a different user via --uid will still drop all capabilities.

**includeDirectory**(path)
Include configuration files from path.

Parameters **path**(str) – The directory to load configuration files from. Each file must end in .conf.

**reloadAllCertificates**()
New in version 1.4.0.
Reload all DNSCrypt and TLS certificates, along with their associated keys.

**setSyslogFacility**(facility)
New in version 1.4.0.
Changed in version 1.6.0: facility can now be a string.
Set the syslog logging facility to facility.

Parameters **or** str **facility**(int) – The new facility as a numeric value (raw value as defined in syslog.h), or as a case-insensitive string ("LOCAL0", or "daemon", for example). Defaults to LOG_DAEMON.

### Listen Sockets

**addLocal**(address[, options])
Changed in version 1.4.0: Removed doTCP from the options. A listen socket on TCP is always created.
Changed in version 1.5.0: Added tcpListenQueueSize parameter.
Changed in version 1.6.0: Added maxInFlight and maxConcurrentTCPConnections parameters.
Changed in version 1.9.0: Added enableProxyProtocol parameter, which was always true before 1.9.0.

Add to the list of listen addresses. Note that for IPv6 link-local addresses, it might be necessary to specify the interface to use: fe80::1%eth0. On recent Linux versions specifying the interface via the interface parameter should work as well.

Parameters

- **address**(str) – The IP Address with an optional port to listen on. The default port is 53.
- **options**(table) – A table with key: value pairs with listen options.

Options:

- doTCP=true: bool - Also bind on TCP on address. Removed in 1.4.0.
- reusePort=false: bool - Set the SO_REUSEPORT socket option.
- tcpFastOpenQueueSize=0: int - Set the TCP Fast Open queue size, enabling TCP Fast Open when available and the value is larger than 0.
- interface="": str - Set the network interface to use.
- cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.
**dnsdist**

- `tcpListenQueueSize=SOMAXCONN`: int - Set the size of the listen queue. Default is SOMAXCONN.
- `maxInFlight=0`: int - Maximum number of in-flight queries. The default is 0, which disables out-of-order processing.
- `maxConcurrentTCPConnections=0`: int - Maximum number of concurrent incoming TCP connections. The default is 0 which means unlimited.
- `enableProxyProtocol=true`: str - Whether to expect a proxy protocol v2 header in front of incoming queries coming from an address in `setProxyProtocolACL()`. Default is true, meaning that queries are expected to have a proxy protocol payload if they come from an address present in the `setProxyProtocolACL() ACL`.

```python
addLocal('0.0.0.0:5300', { reusePort=true })
```

This will bind to both UDP and TCP on port 5300 with SO_REUSEPORT enabled.

```python
addDOHLocal (address[, certFile(s)[, keyFile(s)[, urls[, options ]]]])
```

New in version 1.4.0.

Changed in version 1.5.0: `internalPipeBufferSize`, `sendCacheControlHeaders`, `sessionTimeout`, `trustForwardedForHeader` options added. `url` now defaults to `/dns-query` instead of `/_`, and does exact matching instead of accepting sub-paths. Added `tcpListenQueueSize` parameter.

Changed in version 1.6.0: `enableRenegotiation`, `exactPathMatching`, `maxConcurrentTCPConnections` and `releaseBuffers` options added. `internalPipeBufferSize` now defaults to 1048576 on Linux.

Changed in version 1.8.0: `certFile` now accepts a TLSCertificate object or a list of such objects (see `newTLSCertificate()`), `additionalAddresses`, `ignoreTLSConfigurationErrors` and `keepIncomingHeaders` options added.

Changed in version 1.9.0: `enableProxyProtocol`, `library`, `readAhead` and `proxyProtocolOutsideTLS` options added.

Listen on the specified address and TCP port for incoming DNS over HTTPS connections, presenting the specified X.509 certificate. If no certificate (or key) files are specified, listen for incoming DNS over HTTP connections instead. More information is available in **DNS-over-HTTPS (DoH)**.

**Parameters**

- `address (str)` – The IP Address with an optional port to listen on. The default port is 443.
- `certFile(s) (str)` – The path to a X.509 certificate file in PEM format, a list of paths to such files, or a TLSCertificate object.
- `keyFile(s) (str)` – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the `certFile(s)` ones. Ignored if `certFile` contains TLSCertificate objects.
- `urls (str-or-list)` – The path part of a URL, or a list of paths, to accept queries on. Any query with a path matching exactly one of these will be treated as a DoH query (sub-paths can be accepted by setting the `exactPathMatching` to false). The default is `/dns-query`.
- `options (table)` – A table with key: value pairs with listen options.

**Options:**

- `reusePort=false`: bool - Set the SO_REUSEPORT socket option.
- `tcpFastOpenQueueSize=0`: int - Set the TCP Fast Open queue size, enabling TCP Fast Open when available and the value is larger than 0.
- `interface="": str` - Set the network interface to use.
• cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.

• idleTimeout=30: int - Set the idle timeout, in seconds.

• ciphers: str - The TLS ciphers to use, in OpenSSL format. Ciphers for TLS 1.3 must be specified via ciphersTLS13.

• ciphersTLS13: str - The TLS ciphers to use for TLS 1.3, in OpenSSL format.

• serverTokens: str - The content of the Server: HTTP header returned by dnsdist. The default is "h2o/dnsdist" when h2o is used, "nghttp2-<version>/dnsdist" when nghttp2 is.

• customResponseHeaders={}: table - Set custom HTTP header(s) returned by dnsdist.

• ocspResponses: list - List of files containing OCSP responses, in the same order than the certificates and keys, that will be used to provide OCSP stapling responses.

• minTLSVersion: str - Minimum version of the TLS protocol to support. Possible values are ‘tls1.0’, ‘tls1.1’, ‘tls1.2’ and ‘tls1.3’. Default is to require at least TLS 1.0.

• numberOfTicketsKeys: int - The maximum number of tickets keys to keep in memory at the same time. Only one key is marked as active and used to encrypt new tickets while the remaining ones can still be used to decrypt existing tickets after a rotation. Default to 5.

• ticketKeyFile: str - The path to a file from where TLS tickets keys should be loaded, to support RFC 5077. These keys should be rotated often and never written to persistent storage to preserve forward secrecy. The default is to generate a random key. dnsdist supports several tickets keys to be able to decrypt existing sessions after the rotation. See TLS Sessions Management for more information.

• ticketsKeysRotationDelay: int - Set the delay before the TLS tickets key is rotated, in seconds. Default is 43200 (12h). A value of 0 disables the automatic rotation, which might be useful when ticketKeyFile is used.

• sessionTimeout: int - Set the TLS session lifetime in seconds, this is used both for TLS ticket lifetime and for sessions kept in memory.

• sessionTickets: bool - Whether session resumption via session tickets is enabled. Default is true, meaning tickets are enabled.

• numberOfStoredSessions: int - The maximum number of sessions kept in memory at the same time. Default is 20480. Setting this value to 0 disables stored session entirely.

• preferServerCiphers: bool - Whether to prefer the order of ciphers set by the server instead of the one set by the client. Default is true, meaning that the order of the server is used. For OpenSSL >= 1.1.1, setting this option also enables the temporary re-prioritization of the ChaCha20-Poly1305 cipher if the client prioritizes it.

• keyLogFile: str - Write the TLS keys in the specified file so that an external program can decrypt TLS exchanges, in the format described in https://developer.mozilla.org/en-US/docs/Mozilla/Projects/NSS/Key_Log_Format. Note that this feature requires OpenSSL >= 1.1.1.

• sendCacheControlHeaders: bool - Whether to parse the response to find the lowest TTL and set a HTTP Cache-Control header accordingly. Default is true.

• trustForwardedForHeader: bool - Whether to parse any existing X-Forwarded-For header in the HTTP query and use the right-most value as the client source address and port, for ACL checks, rules, logging and so on. Default is false.

• tcpListenQueueSize=SOMAXCONN: int - Set the size of the listen queue. Default is SOMAXCONN.

• internalPipeBufferSize=0: int - Set the size in bytes of the internal buffer of the pipes used internally to pass queries and responses between threads. Requires support for F_SETPIPE_SZ which is present in Linux since 2.6.35. The actual size might be rounded up to a multiple of a page size. 0 means that the OS default size is used. The default value is 0, except on Linux where it is 1048576 since 1.6.0.
• **exactPathMatching=true**: bool - Whether to do exact path matching of the query path against the paths configured in `urls` (true, the default since 1.5.0) or to accepts sub-paths (false, and was the default before 1.5.0). This option was introduced in 1.6.0.

• **maxConcurrentTCPConnections=0**: int - Maximum number of concurrent incoming TCP connections. The default is 0 which means unlimited.

• **releaseBuffers=true**: bool - Whether OpenSSL should release its I/O buffers when a connection goes idle, saving roughly 35 kB of memory per connection.

• **enableRenegotiation=false**: bool - Whether secure TLS renegotiation should be enabled. Disabled by default since it increases the attack surface and is seldom used for DNS.

• **keepIncomingHeaders**: bool - Whether to retain the incoming headers in memory, to be able to use `HTTPHeaderRule()` or `DNSQuestion.getHTTPHeaders()`. Default is false. Before 1.8.0 the headers were always kept in-memory.

• **additionalAddresses**: list - List of additional addresses (with port) to listen on. Using this option instead of creating a new frontend for each address avoids the creation of new thread and Frontend objects, reducing the memory usage. The drawback is that there will be a single set of metrics for all addresses.

• **ignoreTLSConfigurationErrors=false**: bool - Ignore TLS configuration errors (such as invalid certificate path) and just issue a warning instead of aborting the whole process.

• **library**: str - Which underlying HTTP2 library should be used, either h2o or nghttp2. Until 1.9.0 only h2o was available, but the use of this library is now deprecated as it is no longer maintained. nghttp2 is the new default since 1.9.0.

• **readAhead**: bool - When the TLS provider is set to OpenSSL, whether we tell the library to read as many input bytes as possible, which leads to better performance by reducing the number of syscalls. Default is true.

• **proxyProtocolOutsideTLS**: bool - Whether the payload is prepended after the start of the TLS session (so inside, meaning it is protected by the TLS layer providing encryption and authentication) or not (outside, meaning it is in clear-text). Default is false which means inside. Note that most third-party software like HAproxy expect the proxy protocol payload to be outside, in clear-text.

• **enableProxyProtocol=true**: str - Whether to expect a proxy protocol v2 header in front of incoming queries coming from an address in `setProxyProtocolACL()`. Default is true, meaning that queries are expected to have a proxy protocol payload if they come from an address present in the `setProxyProtocolACL()` ACL.

`addDOH3Local(address, certFile(s), keyFile(s), options)`

New in version 1.9.0.

Listen on the specified address and UDP port for incoming DNS over HTTP3 connections, presenting the specified X.509 certificate. More information is available in `DNS-over-HTTP/3 (DoH3)`.

**Parameters**

- **address**(str) – The IP Address with an optional port to listen on. The default port is 443.

- **certFile(s)**(str) – The path to a X.509 certificate file in PEM format, a list of paths to such files, or a TLSCertificate object.

- **keyFile(s)**(str) – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the certFile(s) ones. Ignored if certFile contains TLSCertificate objects.

- **options**(table) – A table with key: value pairs with listen options.

**Options:**

- **reusePort=false**: bool - Set the SO_REUSEPORT socket option.
• interface="": str - Set the network interface to use.

• cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.

• idleTimeout=5: int - Set the idle timeout, in seconds.

• internalPipeBufferSize=0: int - Set the size in bytes of the internal buffer of the pipes used internally to pass queries and responses between threads. Requires support for F_SETPIPE_SZ which is present in Linux since 2.6.35. The actual size might be rounded up to a multiple of a page size. 0 means that the OS default size is used. The default value is 0, except on Linux where it is 1048576 since 1.6.0.

• maxInFlight=65535: int - Maximum number of in-flight queries. The default is 0, which disables out-of-order processing.

• congestionControlAlgo="reno": str - The congestion control algorithm to be chosen between reno, cubic and bbr.

• keyLogFile: str - Write the TLS keys in the specified file so that an external program can decrypt TLS exchanges, in the format described in https://developer.mozilla.org/en-US/docs/Mozilla/Projects/NSS/Key_Log_Format.

addDOQLocal (address, certFile(s), keyFile(s)[, options])

New in version 1.9.0.

Listen on the specified address and UDP port for incoming DNS over QUIC connections, presenting the specified X.509 certificate.

Parameters

• address (str) – The IP Address with an optional port to listen on. The default port is 853.

• certFile(s) (str) – The path to a X.509 certificate file in PEM format, a list of paths to such files, or a TLSCertificate object.

• keyFile(s) (str) – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the certFile(s) ones. Ignored if certFile contains TLSCertificate objects.

• options (table) – A table with key: value pairs with listen options.

Options:

• reusePort=false: bool - Set the SO_REUSEPORT socket option.

• interface="": str - Set the network interface to use.

• cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.

• idleTimeout=5: int - Set the idle timeout, in seconds.

• internalPipeBufferSize=0: int - Set the size in bytes of the internal buffer of the pipes used internally to pass queries and responses between threads. Requires support for F_SETPIPE_SZ which is present in Linux since 2.6.35. The actual size might be rounded up to a multiple of a page size. 0 means that the OS default size is used. The default value is 0, except on Linux where it is 1048576 since 1.6.0.

• maxInFlight=65535: int - Maximum number of in-flight queries. The default is 0, which disables out-of-order processing.

• congestionControlAlgo="reno": str - The congestion control algorithm to be chosen between reno, cubic and bbr.
• keyLogFile: str - Write the TLS keys in the specified file so that an external program can decrypt TLS exchanges, in the format described in https://developer.mozilla.org/en-US/docs/Mozilla/Projects/NSS/Key_Log_Format.

addTLSLocal (address, certFile(s), keyFile(s)[, options])

Changed in version 1.4.0: ciphersTLS13, minTLSVersion, ocspResponses, preferServerCiphers, keyLogFile options added.

Changed in version 1.5.0: sessionTimeout and tcpListenQueueSize options added.

Changed in version 1.6.0: enableRenegotiation, maxConcurrentTCPConnections, maxInFlight and releaseBuffers options added.

Changed in version 1.8.0: tlsAsyncMode option added.

Changed in version 1.8.0: certFile now accepts a TLSCertificate object or a list of such objects (see newTLSCertificate()), additionalAddresses, ignoreTLSConfigurationErrors and ktls options added.

Changed in version 1.9.0: enableProxyProtocol, readAhead and proxyProtocolOutsideTLS options added.

Listen on the specified address and TCP port for incoming DNS over TLS connections, presenting the specified X.509 certificate.

Parameters

• address (str) – The IP Address with an optional port to listen on. The default port is 853.

• certFile(s) (str) – The path to a X.509 certificate file in PEM format, a list of paths to such files, or a TLSCertificate object.

• keyFile(s) (str) – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the certFile(s) ones. Ignored if certFile contains TLSCertificate objects.

• options (table) – A table with key: value pairs with listen options.

Options:

• reusePort=false: bool - Set the SO_REUSEPORT socket option.

• tcpFastOpenQueueSize=0: int - Set the TCP Fast Open queue size, enabling TCP Fast Open when available and the value is larger than 0.

• interface="": str - Set the network interface to use.

• cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.

• provider: str - The TLS library to use between GnuTLS and OpenSSL, if they were available and enabled at compilation time. Default is to use OpenSSL when available.

• ciphers: str - The TLS ciphers to use. The exact format depends on the provider used. When the OpenSSL provider is used, ciphers for TLS 1.3 must be specified via ciphersTLS13.

• ciphersTLS13: str - The ciphers to use for TLS 1.3, when the OpenSSL provider is used. When the GnuTLS provider is used, ciphers applies regardless of the TLS protocol and this setting is not used.

• numberOfTicketsKeys: int - The maximum number of tickets keys to keep in memory at the same time, if the provider supports it (GnuTLS doesn’t, OpenSSL does). Only one key is marked as active and used to encrypt new tickets while the remaining ones can still be used to decrypt existing tickets after a rotation. Default to 5.

• ticketKeyFile: str - The path to a file from where TLS tickets keys should be loaded, to support RFC 5077. These keys should be rotated often and never written to persistent storage to preserve
forward secrecy. The default is to generate a random key. The OpenSSL provider supports several
tickets keys to be able to decrypt existing sessions after the rotation, while the GnuTLS provider only
supports one key. See TLS Sessions Management for more information.

- **ticketsKeysRotationDelay**: int - Set the delay before the TLS tickets key is rotated, in sec-
  onds. Default is 43200 (12h). A value of 0 disables the automatic rotation, which might be useful
  when ticketKeyFile is used.

- **sessionTimeout**: int - Set the TLS session lifetime in seconds, this is used both for TLS ticket
  lifetime and for sessions kept in memory.

- **sessionTickets**: bool - Whether session resumption via session tickets is enabled. Default is
  true, meaning tickets are enabled.

- **numberOfStoredSessions**: int - The maximum number of sessions kept in memory at the same
time. At this time this is only supported by the OpenSSL provider, as stored sessions are not supported
  with the GnuTLS one. Default is 20480. Setting this value to 0 disables stored session entirely.

- **ocspResponses**: list - List of files containing OCSP responses, in the same order than the certifi-
cates and keys, that will be used to provide OCSP stapling responses.

- **minTLSVersion**: str - Minimum version of the TLS protocol to support. Possible values are ‘tls1.0’,
  ‘tls1.1’, ‘tls1.2’ and ‘tls1.3’. Default is to require at least TLS 1.0. Note that this value is ignored
  when the GnuTLS provider is in use, and the ciphers option should be set accordingly instead. For
  example, ‘NORMAL:!VERS-TLS1.0:!VERS-TLS1.1’ will disable TLS 1.0 and 1.1.

- **preferServerCiphers**: bool - Whether to prefer the order of ciphers set by the server instead of
  the one set by the client. Default is true, meaning that the order of the server is used. For OpenSSL
  >= 1.1.1, setting this option also enables the temporary re-prioritization of the ChaCha20-Poly1305
  cipher if the client prioritizes it.

- **keyLogFile**: str - Write the TLS keys in the specified file so that an external program can decrypt
  TLS exchanges, in the format described in https://developer.mozilla.org/en-US/docs/Mozilla/Projects/
  NSS/Key_Log_Format. Note that this feature requires OpenSSL >= 1.1.1.

- **tcpListenQueueSize=SOMAXCONN**: int - Set the size of the listen queue. Default is
  SOMAXCONN.

- **maxInFlight=0**: int - Maximum number of in-flight queries. The default is 0, which disables
  out-of-order processing.

- **maxConcurrentTCPConnections=0**: int - Maximum number of concurrent incoming TCP con-
  nections. The default is 0 which means unlimited.

- **releaseBuffers=true**: bool - Whether OpenSSL should release its I/O buffers when a connec-
  tion goes idle, saving roughly 35 kB of memory per connection.

- **enableRenegotiation=false**: bool - Whether secure TLS renegotiation should be enabled
  (OpenSSL only, the GnuTLS provider does not support it). Disabled by default since it increases
  the attack surface and is seldom used for DNS.

- **tlsAsyncMode=false**: bool - Whether to enable experimental asynchronous TLS I/O operations
  if OpenSSL is used as the TLS implementation and an asynchronous capable SSL engine (or provider)
  is loaded. See also loadTLSEngine() or loadTLSProvider() to load the engine (or provider).

- **additionalAddresses**: list - List of additional addresses (with port) to listen on. Using this
  option instead of creating a new frontend for each address avoids the creation of new thread and
  Frontend objects, reducing the memory usage. The drawback is that there will be a single set of
  metrics for all addresses.

- **ignoreTLSConfigurationErrors=false**: bool - Ignore TLS configuration errors (such as
  invalid certificate path) and just issue a warning instead of aborting the whole process.

- **ktls=false**: bool - Whether to enable the experimental kernel TLS support on Linux, if both the
  kernel and the OpenSSL library support it. Default is false.
• **readAhead**: bool - When the TLS provider is set to OpenSSL, whether we tell the library to read as many input bytes as possible, which leads to better performance by reducing the number of syscalls. Default is true.

• **proxyProtocolOutsideTLS**: bool - When the use of incoming proxy protocol is enabled, whether the payload is prepended after the start of the TLS session (so inside, meaning it is protected by the TLS layer providing encryption and authentication) or not (outside, meaning it is in clear-text). Default is false which means inside. Note that most third-party software like HAproxy expect the proxy protocol payload to be outside, in clear-text.

• **enableProxyProtocol=true**: str - Whether to expect a proxy protocol v2 header in front of incoming queries coming from an address in `setProxyProtocolACL()`. Default is true, meaning that queries are expected to have a proxy protocol payload if they come from an address present in the `setProxyProtocolACL() ACL`.

**setLocal**( `address`, `options` )
Remove the list of listen addresses and add a new one.

**Parameters**

• **address**(str) – The IP Address with an optional port to listen on. The default port is 53.

• **options**(table) – A table with key: value pairs with listen options.

The options that can be set are the same as `addLocal()`.

**Control Socket, Console and Webserver**

**addConsoleACL**( `netmask` )
Add a netmask to the existing console ACL, allowing remote clients to connect to the console. Please make sure that encryption has been enabled with `setKey()` before doing so. The default is to only allow 127.0.0.1/8 and ::1/128.

**Parameters** **netmask**(str) – A CIDR netmask, e.g. "192.0.2.0/24". Without a sub-netmask, only the specific address is allowed.

**clearConsoleHistory()**
New in version 1.6.0.
Clear the internal (in-memory) buffers of console commands. These buffers are used to provide the `delta()` command and console completion and history, and can end up being quite large when a lot of commands are issued via the console, consuming a noticeable amount of memory.

**controlSocket**( `address` )
Bind to `addr` and listen for a connection for the console. Since 1.3.0 only connections from local users are allowed by default, `addConsoleACL()` and `setConsoleACL()` can be used to enable remote connections. Please make sure that encryption has been enabled with `setKey()` before doing so. Enabling encryption is also strongly advised for local connections, since not enabling it allows any local user to connect to the console.

**Parameters** **address**(str) – An IP address with optional port. By default, the port is 5199.

**delta()**
Issuing `delta` on the console will print the changes to the configuration that have been made since startup.

**inClientStartup()**
Returns true while the console client is parsing the configuration.

**inConfigCheck()**
New in version 1.5.0.
Returns true while the configuration is being checked, ie when run with `--check-config`.

**makeKey()**
Generate and print an encryption key.
**setConsoleConnectionsLogging** *(enabled)*

Whether to log the opening and closing of console connections.

Parameters

- **enabled** *(bool)* – Default to true.

**setConsoleMaximumConcurrentConnections** *(max)*

New in version 1.6.0.

Set the maximum number of concurrent console connections.

Parameters

- **max** *(int)* – The maximum number of concurrent console connections, or 0 which means an unlimited number. Defaults to 100

**setKey**(key)

Use *key* as shared secret between the client and the server

Parameters

- **key** *(str)* – An encoded key, as generated by *makeKey()*

**setConsoleACL**(netmasks)

Remove the existing console ACL and add the netmasks from the table, allowing remote clients to connect to the console. Please make sure that encryption has been enabled with *setKey()* before doing so.

Parameters

- **netmasks** *(str)* – A table of CIDR netmask, e.g. {"192.0.2.0/24", "2001:DB8:14::/56"}. Without a subnetmask, only the specific address is allowed.

**showConsoleACL**

Print a list of all netmasks allowed to connect to the console.

**testCrypto**

Test the crypto code, will report errors when something is not ok.

**setConsoleOutputMaxMsgSize**(size)

Set the maximum size in bytes of a single console message, default set to 10 MB.

Parameters

- **size** *(int)* – The new maximum size.

**Webserver configuration**

**hashPassword**(password[, workFactor])

New in version 1.7.0.

Hash the supplied password using a random salt, and returns a string that can be used with *setWebserverConfig()*.

Parameters

- **password** *(string)* – The password to hash
- **workFactor** *(int)* – The work factor to use for the hash function (currently scrypt), as a power of two. Default is 1024.

**webserver**(listen_address[, password[, apikey[, customHeaders[, acl ]]]]])

Changed in version 1.5.0: acl optional parameter added.

Changed in version 1.6.0: The *password* parameter is now optional. The use of optional parameters is now deprecated. Please use *setWebserverConfig()* instead.

Changed in version 1.8.0: The *password*, *apikey*, *customHeaders* and *acl* parameters is no longer supported. Please use *setWebserverConfig()* instead.

Launch the *Built-in webserver* with statistics and the API. Note that the parameters are global, so the parameter from the last *webserver* will override any existing ones. For this reason *setWebserverConfig()* should be used instead of specifying optional parameters here.

Parameters

- **listen_address** *(str)* – The IP address and Port to listen on
- **password** *(str)* – The password required to access the webserver
**apikey** *(str)* – The key required to access the API

**customHeaders** *(\{[str] = str, ...\})* – Allows setting custom headers and removing the defaults

**acl** *(str)* – List of netmasks, as a string, that are allowed to open a connection to the web server. Defaults to “127.0.0.1, ::1”. It accepts the same syntax that `NetmaskGroup.addMask()` does

```python
setAPIWritable(allow[, dir])
```

Allow modifications via the API. Optionally saving these changes to disk. Modifications done via the API will not be written to the configuration by default and will not persist after a reload.

**Parameters**

- **allow** *(bool)* – Set to true to allow modification through the API
- **dir** *(str)* – A valid directory where the configuration files will be written by the API.

```python
setWebserverConfig(options)
```

Changed in version 1.5.0: acl optional parameter added.

Changed in version 1.6.0: statsRequireAuthentication, maxConcurrentConnections optional parameters added.

Changed in version 1.7.0: The optional password and apiKey parameters now accept hashed passwords. The optional hashPlaintextCredentials parameter has been added.

Changed in version 1.8.0: apiRequiresAuthentication, dashboardRequiresAuthentication optional parameters added.

Setup webserver configuration. See `webserver()`.

**Parameters**

- **options** *(table)* – A table with key: value pairs with webserver options.

**Options**

- **password=newPassword** *(string)*: Set the password used to access the internal webserver. Since 1.7.0 the password should be hashed and salted via the `hashPassword()` command.
- **apiKey=newKey** *(string)*: Changes the API Key (set to an empty string do disable it). Since 1.7.0 the key should be hashed and salted via the `hashPassword()` command.
- **customHeaders={}[str]=str,...\}**: map of string - Allows setting custom headers and removing the defaults.
- **acl=newACL** *(string)*: List of IP addresses, as a string, that are allowed to open a connection to the web server. Defaults to “127.0.0.1, ::1”.
- **apiRequiresAuthentication** *(bool)*: Whether access to the API (/api endpoints) require a valid API key. Defaults to true.
- **dashboardRequiresAuthentication** *(bool)*: Whether access to the internal dashboard requires a valid password. Defaults to true.
- **statsRequireAuthentication** *(bool)*: Whether access to the statistics (/metrics and /jsonstat endpoints) require a valid password or API key. Defaults to true.
- **maxConcurrentConnections** *(int)*: The maximum number of concurrent web connections, or 0 which means an unlimited number. Defaults to 100.
- **hashPlaintextCredentials** *(bool)*: Whether passwords and API keys provided in plaintext should be hashed during startup, to prevent the plaintext versions from staying in memory. Doing so increases significantly the cost of verifying credentials. Defaults to false.

```python
registerWebHandler(path, handler)
```

Register a function named handler that will be called for every query sent to the exact path path. The function will receive a `WebRequest` object and a `WebResponse` object, representing respectively the HTTP request received and the HTTP response to send. For example a handler registered for ‘/foo’ will receive these queries:
• GET /foo
• POST /foo
• GET /foo?param=1

But not queries for /foobar or /foo/bar.

A sample handler function could be:

```lua
function customHTTPHandler(req, resp)
  local get = req.getvars
  local headers = req.headers

  if req.path ~= '/foo' or req.version ~= 11 or req.method ~= 'GET' or get['param'] ~= '42' or headers['custom'] ~= 'foobar' then
    resp.status = 500
    return
  end

  resp.status = 200
  resp.body = 'It works!'
  resp.headers = { ['Foo'] = 'Bar' }
end

registerWebHandler('/foo', customHTTPHandler)
```

**Parameters**

- **path** *(str)* – Path to register the handler for.
- **handler** *(function)* – The Lua function to register.

**showWebserverConfig()**

New in version 1.7.0.

Show the current webserver configuration. See `webserver()`.

**Access Control Lists**

**addACL** *(netmask)*

Add a netmask to the existing ACL controlling which clients can send UDP, TCP, DNS over TLS and DNS over HTTPS queries. See `Access Control` for more information.

**Parameters**

- **netmask** *(str)* – A CIDR netmask, e.g. "192.0.2.0/24". Without a subnetmask, only the specific address is allowed.

**rmACL** *(netmask)*

Remove a network from the existing ACL controlling which clients can send UDP, TCP, DNS over TLS and DNS over HTTPS queries. See `Access Control` for more information. This function only removes previously added entries, it does not remove subnets of entries.

**Parameters**

- **netmask** *(str)* – A CIDR netmask, e.g. "192.0.2.0/24". Without a subnetmask, only the specific address is allowed.

```
addACL("192.0.2.0/24")  -- for example add subnet to the ACL
rmACL("192.0.2.10")    -- does NOT work, the ACL is unchanged
rmACL("192.0.2.0/24")  -- does work, the exact match is removed from the ACL
```

**setACL** *(netmasks)*

Remove the existing ACL and add the netmasks from the table of those allowed to send UDP, TCP, DNS over TLS and DNS over HTTPS queries. See `Access Control` for more information.

...
**Parameters netmasks** ((str)) – A table of CIDR netmask, e.g. "{192.0.2.0/24", "2001:DB8:14::/56"}. Without a subnetmask, only the specific address is allowed.

**setACLFromFile**(fname)
New in version 1.6.0.
Reset the ACL to the list of netmasks from the given file. See Access Control for more information.

**Parameters fname**(str) – The path to a file containing a list of netmasks. Empty lines or lines starting with “#” are ignored.

**setProxyProtocolACL**(netmasks)
New in version 1.6.0.
Set the list of netmasks from which a Proxy Protocol header will be required, over UDP, TCP and DNS over TLS. The default is empty. Note that a proxy protocol payload will be required from these clients, regular DNS queries will no longer be accepted if they are not preceded by a proxy protocol payload. Be also aware that, if setProxyProtocolApplyACLToProxiedClients() is set (default is false), the general ACL will be applied to the source IP address as seen by dnssdist first, but also to the source IP address provided in the Proxy Protocol header.

**Parameters netmasks** ((str)) – A table of CIDR netmask, e.g. "{192.0.2.0/24", "2001:DB8:14::/56"}. Without a subnetmask, only the specific address is allowed.

**setProxyProtocolApplyACLToProxiedClients**(apply)
New in version 1.6.0.
Whether the general ACL should be applied to the source IP address provided in the Proxy Protocol header, in addition to being applied to the source IP address as seen by dnssdist first.

**Parameters apply**(bool) – Whether it should be applied or not (default is false).

**showACL()**
Print a list of all netmasks allowed to send queries over UDP, TCP, DNS over TLS and DNS over HTTPS. See Access Control for more information.

**EDNS Client Subnet**

**setECSOverride**(bool)
When useClientSubnet in newServer() is set and dnssdist adds an EDNS Client Subnet Client option to the query, override an existing option already present in the query, if any. Note that it’s not recommended to enable setECSOverride in front of an authoritative server responding with EDNS Client Subnet information as mismatching data (ECS scopes) can confuse clients and lead to SERVFAIL responses on downstream nameservers.

**Parameters bool** – Whether to override an existing EDNS Client Subnet option present in the query. Defaults to false

**setECSSourcePrefixV4**(prefix)
When useClientSubnet in newServer() is set and dnssdist adds an EDNS Client Subnet Client option to the query, truncate the requestors IPv4 address to prefix bits

**Parameters prefix**(int) – The prefix length

**setECSSourcePrefixV6**(prefix)
When useClientSubnet in newServer() is set and dnssdist adds an EDNS Client Subnet Client option to the query, truncate the requestor’s IPv6 address to bits

**Parameters prefix**(int) – The prefix length

**Ringbuffers**

**setRingBuffersLockRetries**(num)
Deprecated since version 1.8.0: Deprecated in 1.8.0 in favor of setRingBuffersOptions() which
dnsdist provides more options.

Set the number of shards to attempt to lock without blocking before giving up and simply blocking while waiting for the next shard to be available

**Parameters** 
`num` *(int)* – The maximum number of attempts. Defaults to 5 if there is more than one shard, 0 otherwise.

**setRingBuffersOptions**(options)

New in version 1.8.0.

Set the rings buffers configuration

**Parameters** 
`options` *(table)* – A table with key: value pairs with options.

Options:

- **lockRetries**: int - Set the number of shards to attempt to lock without blocking before giving up and simply blocking while waiting for the next shard to be available. Default to 5 if there is more than one shard, 0 otherwise
- **recordQueries**: boolean - Whether to record queries in the ring buffers. Default is true. Note that `grepq()`, several `top*` commands (`topClients()`, `topQueries()`...) and the Dynamic Blocks require this to be enabled.
- **recordResponses**: boolean - Whether to record responses in the ring buffers. Default is true. Note that `grepq()`, several `top*` commands (`topResponses()`, `topSlow()`...) and the Dynamic Blocks require this to be enabled.

**setRingBuffersSize**(num, numberOfShards)

Changed in version 1.6.0: `numberOfShards` defaults to 10.

Set the capacity of the ringbuffers used for live traffic inspection to `num`, and the number of shards to `numberOfShards` if specified. Increasing the number of entries comes at both a memory cost (around 250 MB for 1 million entries) and a CPU processing cost, so we strongly advise not going over 1 million entries.

**Parameters**

- **num**: int – The maximum amount of queries to keep in the ringbuffer. Defaults to 10000
- **numberOfShards**: int – the number of shards to use to limit lock contention. Default is 10, used to be 1 before 1.6.0

### 19.1.3 Servers

**newServer**(server_string)

**newServer**(server_table)

Changed in version 1.4.0: Added `checkInterval`, `checkTimeout` and `rise` to `server_table`.

Changed in version 1.5.0: Added `useProxyProtocol` to `server_table`.

Changed in version 1.6.0: Added `maxInFlight` to `server_table`.

Changed in version 1.7.0: Added `addXForwardedHeaders`, `caStore`, `checkTCP`, `ciphers`, `ciphers13`, `dohPath`, `enableRenegotiation`, `releaseBuffers`, `subjectName`, `tcpOnly`, `tls` and `validateCertificates` to `server_table`.

Changed in version 1.8.0: Added `autoUpgrade`, `autoUpgradeDoHKey`, `autoUpgradeInterval`, `autoUpgradeKeep`, `autoUpgradePool`, `maxConcurrentTCPConnections`, `subjectAddr`, `lazyHealthCheckSampleSize`, `lazyHealthCheckMinSampleCount`, `lazyHealthCheckThreshold`, `lazyHealthCheckFailedInterval`, `lazyHealthCheckMode`, `lazyHealthCheckUseExponentialBackOff`, `lazyHealthCheckMaxBackOff`, `lazyHealthCheckWhenUpgraded`, `healthCheckMode` and `ktls` to `server_table`. 
Changed in version 1.9.0: Added `proxyProtocolAdvertiseTLS` to `server_table`.

**Parameters**

- `server_string (str)` – A simple IP:PORT string.
- `server_table (table)` – A table with at least an `address` key

Add a new backend server. Call this function with either a string:

```python
newServer(
    "IP:PORT" -- IP and PORT of the backend server
)
```

or a table:

```python
newServer({ ... })
```

where the elements in the table can be:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>ip:port</td>
<td>ip and port of the backend server (mandatory)</td>
</tr>
<tr>
<td>id</td>
<td>string</td>
<td>Use a pre-defined UUID instead of a random one</td>
</tr>
<tr>
<td>qps</td>
<td>number</td>
<td>Limit the number of queries per second to <code>number</code>, when using the <code>firstAvailable</code> policy</td>
</tr>
<tr>
<td>order</td>
<td>number</td>
<td>The order of this server, used by the <code>leastOutstanding</code> and <code>firstAvailable</code> policies</td>
</tr>
<tr>
<td>weight</td>
<td>number</td>
<td>The weight of this server, used by the <code>wrandom</code>, <code>whashed</code> and <code>chashed</code> policies, default: 1. Supported values are a minimum of 1, and a maximum of 2147483647.</td>
</tr>
<tr>
<td>pool</td>
<td>string</td>
<td>The pools this server belongs to (unset or empty string means default pool) as a string or table of strings</td>
</tr>
<tr>
<td>retries</td>
<td>number</td>
<td>The number of TCP connection attempts to the backend, for a given query</td>
</tr>
<tr>
<td>tcpConnectTimeout</td>
<td>number</td>
<td>The timeout (in seconds) of a TCP connection attempt</td>
</tr>
<tr>
<td>tcpSendTimeout</td>
<td>number</td>
<td>The timeout (in seconds) of a TCP write attempt</td>
</tr>
<tr>
<td>tcpRecvTimeout</td>
<td>number</td>
<td>The timeout (in seconds) of a TCP read attempt</td>
</tr>
<tr>
<td>tcpFastOpen</td>
<td>bool</td>
<td>Whether to enable TCP Fast Open</td>
</tr>
<tr>
<td>ipBindAddrNoPort</td>
<td>bool</td>
<td>Whether to enable IP_BIND_ADDRESS_NO_PORT if available, default: true</td>
</tr>
<tr>
<td>name</td>
<td>string</td>
<td>The name associated to this backend, for display purpose</td>
</tr>
</tbody>
</table>

### Table 1 – continued from previous page

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkClass</td>
<td>number</td>
<td>Use number as QCLASS in the health-check query, default: DNSClass.IN</td>
</tr>
<tr>
<td>checkName</td>
<td>string</td>
<td>Use string as QNAME in the health-check query, default: &quot;a.root-servers.net.&quot;</td>
</tr>
<tr>
<td>checkType</td>
<td>string</td>
<td>Use string as QTYPE in the health-check query, default: &quot;A&quot;</td>
</tr>
<tr>
<td>checkFunction</td>
<td>function</td>
<td>Use this function to dynamically set the QNAME, QTYPE and QCLASS to use in the health-check query (see Healthcheck)</td>
</tr>
<tr>
<td>checkTimeout</td>
<td>number</td>
<td>The timeout (in milliseconds) of a health-check query, default: 1000 (1s)</td>
</tr>
<tr>
<td>setCD</td>
<td>bool</td>
<td>Set the CD (Checking Disabled) flag in the health-check query, default: false</td>
</tr>
<tr>
<td>maxCheckFailures</td>
<td>number</td>
<td>Allow number check failures before declaring the backend down, default: 1</td>
</tr>
<tr>
<td>checkInterval</td>
<td>number</td>
<td>The time in seconds between health checks</td>
</tr>
<tr>
<td>mustResolve</td>
<td>bool</td>
<td>Set to true when the health check MUST return a RCODE different from NXDomain, ServFail and Refused. Default is false, meaning that every RCODE except ServFail is considered valid</td>
</tr>
<tr>
<td>useClientSubnet</td>
<td>bool</td>
<td>Add the client's IP address in the EDNS Client Subnet option when forwarding the query to this backend</td>
</tr>
</tbody>
</table>
| source               | string     | The source address or interface to use for queries to this backend. The following formats are supported:  
  - address, e.g. "192.0.2.2"  
  - interface name, e.g. "eth0"  
  - address@interface, e.g. "192.0.2.2@eth0" |

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addXPF</td>
<td>number</td>
<td>Add the client’s IP address and port to the query, along with the original destination address and port, using the experimental XPF record from draft-bellis-dnsop-xpf and the specified option code. Default is disabled (0). This is a deprecated feature that will be removed in the near future.</td>
</tr>
<tr>
<td>sockets</td>
<td>number</td>
<td>Number of UDP sockets (and thus source ports) used toward the backend server, defaults to a single one. Note that for backends which are multithreaded, this setting will have an effect on the number of cores that will be used to process traffic from dnsdist. For example you may want to set ‘sockets’ to a number somewhat higher than the number of worker threads configured in the backend, particularly if the Linux kernel is being used to distribute traffic to multiple threads listening on the same socket (via reuseport). See also setRandomizedOutgoingSockets().</td>
</tr>
<tr>
<td>disableZeroScope</td>
<td>bool</td>
<td>Disable the EDNS Client Subnet ‘zero scope’ feature, which does a cache lookup for an answer valid for all subnets (ECS scope of 0) before adding ECS information to the query and doing the regular lookup. This requires the parseECS option of the corresponding cache to be set to true.</td>
</tr>
<tr>
<td>rise</td>
<td>number</td>
<td>Require number consecutive successful checks before declaring the backend up, default: 1</td>
</tr>
<tr>
<td>useProxyProtocol</td>
<td>bool</td>
<td>Add a proxy protocol header to the query, passing along the client’s IP address and port along with the original destination address and port. Default is disabled.</td>
</tr>
<tr>
<td>reconnectOnUp</td>
<td>bool</td>
<td>Close and reopen the sockets when a server transits from Down to Up. This helps when an interface is missing when dnsdist is started. Default is disabled.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>maxInFlight</td>
<td>number</td>
<td>Maximum number of in-flight queries. The default is 0, which disables out-of-order processing. It should only be enabled if the backend does support out-of-order processing. As of 1.6.0, out-of-order processing needs to be enabled on the frontend as well, via <code>addLocal()</code> and/or <code>addTLSLocal()</code>. Note that out-of-order is always enabled on DoH frontends.</td>
</tr>
<tr>
<td>tcpOnly</td>
<td>bool</td>
<td>Always forward queries to that backend over TCP, never over UDP. Always enabled for TLS backends. Default is false.</td>
</tr>
<tr>
<td>checkTCP</td>
<td>bool</td>
<td>Whether to do healthcheck queries over TCP, instead of UDP. Always enabled for DNS over TLS backend. Default is false.</td>
</tr>
<tr>
<td>tls</td>
<td>string</td>
<td>Enable DNS over TLS communications for this backend, or DNS over HTTPS if <code>dohPath</code> is set, using the TLS provider (&quot;openssl&quot; or &quot;gnutls&quot;) passed in parameter. Default is an empty string, which means this backend is used for plain UDP and TCP.</td>
</tr>
<tr>
<td>caStore</td>
<td>string</td>
<td>Specifies the path to the CA certificate file, in PEM format, to use to check the certificate presented by the backend. Default is an empty string, which means to use the system CA store. Note that this directive is only used if <code>validateCertificates</code> is set.</td>
</tr>
<tr>
<td>ciphers</td>
<td>string</td>
<td>The TLS ciphers to use. The exact format depends on the provider used. When the OpenSSL provider is used, ciphers for TLS 1.3 must be specified via <code>ciphersTLS13</code>.</td>
</tr>
<tr>
<td>ciphersTLS13</td>
<td>string</td>
<td>The ciphers to use for TLS 1.3, when the OpenSSL provider is used. When the GnuTLS provider is used, <code>ciphers</code> applies regardless of the TLS protocol and this setting is not used.</td>
</tr>
</tbody>
</table>
Table 1 – continued from previous page

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subjectName</td>
<td>string</td>
<td>The subject name passed in the SNI value of the TLS handshake, and against which to validate the certificate presented by the backend. Default is empty. If set this value supersedes any subjectAddr one.</td>
</tr>
<tr>
<td>subjectAddr</td>
<td>string</td>
<td>The subject IP address passed in the SNI value of the TLS handshake, and against which to validate the certificate presented by the backend. Default is empty.</td>
</tr>
<tr>
<td>validateCertificates</td>
<td>bool</td>
<td>Whether the certificate presented by the backend should be validated against the CA store (see caStore). Default is true.</td>
</tr>
<tr>
<td>dohPath</td>
<td>string</td>
<td>Enable DNS over HTTPS communication for this backend, using POST queries to the HTTP host supplied as subjectName and the HTTP path supplied in this parameter.</td>
</tr>
<tr>
<td>addXForwardedHeaders</td>
<td>bool</td>
<td>Whether to add X-Forwarded-For, X-Forwarded-Port and X-Forwarded-Proto headers to a DNS over HTTPS backend.</td>
</tr>
<tr>
<td>releaseBuffers</td>
<td>bool</td>
<td>Whether OpenSSL should release its I/O buffers when a connection goes idle, saving roughly 35 kB of memory per connection. Default to true.</td>
</tr>
<tr>
<td>enableRenegotiation</td>
<td>bool</td>
<td>Whether secure TLS renegotiation should be enabled. Disabled by default since it increases the attack surface and is seldom used for DNS.</td>
</tr>
<tr>
<td>autoUpgrade</td>
<td>bool</td>
<td>Whether to use the ‘Discovery of Designated Resolvers’ mechanism to automatically upgrade a Do53 backend to DoT or DoH, depending on the priorities present in the SVCB record returned by the backend. Default to false.</td>
</tr>
<tr>
<td>autoUpgradeInterval</td>
<td>number</td>
<td>If autoUpgrade is set, how often to check if an upgrade is available, in seconds. Default is 3600 seconds.</td>
</tr>
<tr>
<td>autoUpgradeKeep</td>
<td>bool</td>
<td>If autoUpgrade is set, whether to keep the existing Do53 backend around after an upgrade. Default is false which means the Do53 backend will be replaced by the upgraded one.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>autoUpgradePool</td>
<td>string</td>
<td>If <code>autoUpgrade</code> is set, in which pool to place the newly upgraded backend. Default is empty which means the backend is placed in the default pool.</td>
</tr>
<tr>
<td>autoUpgradeDoHKey</td>
<td>number</td>
<td>If <code>autoUpgrade</code> is set, the value to use for the SVC key corresponding to the DoH path. Default is 7.</td>
</tr>
<tr>
<td>maxConcurrentTCPConnections</td>
<td>number</td>
<td>Maximum number of TCP connections to that backend. When that limit is reached, queries routed to that backend that cannot be forwarded over an existing connection will be dropped. Default is 0 which means no limit.</td>
</tr>
<tr>
<td>healthCheckMode</td>
<td>string</td>
<td>The health-check mode to use: ‘auto’ which sends health-check queries every <code>checkInterval</code> seconds, ‘up’ which considers that the backend is always available, ‘down’ that it is always not available, and ‘lazy’ which only sends health-check queries after a configurable amount of regular queries have failed (see <code>lazyHealthCheckSampleSize</code>, <code>lazyHealthCheckMinSampleCount</code>, <code>lazyHealthCheckThreshold</code>, <code>lazyHealthCheckFailedInterval</code> and <code>lazyHealthCheckMode</code> for more information). Default is ‘auto’. See <code>Healthcheck</code> for a more detailed explanation.</td>
</tr>
<tr>
<td>lazyHealthCheckFailedInterval</td>
<td>number</td>
<td>The interval, in seconds, between health-check queries in ‘lazy’ mode. Note that when <code>lazyHealthCheckUseExponentialBackOff</code> is set to true, the interval doubles between every queries. These queries are only sent when a threshold of failing regular queries has been reached, and until the backend is available again. Default is 30 seconds.</td>
</tr>
<tr>
<td>lazyHealthCheckMinSampleCount</td>
<td>number</td>
<td>The minimum amount of regular queries that should have been recorded before the <code>lazyHealthCheckThreshold</code> threshold can be applied. Default is 1 which means only one query is needed.</td>
</tr>
</tbody>
</table>

Continued on next page
<table>
<thead>
<tr>
<th>Keyword</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lazyHealthCheckMode</td>
<td>string</td>
<td>The ‘lazy’ health-check mode: ‘TimeoutOnly’ means that only timeout and I/O errors of regular queries will be considered for the lazyHealthCheckThreshold, while ‘TimeoutOrServFail’ will also consider ‘Server Failure’ answers. Default is ‘TimeoutOrServFail’.</td>
</tr>
<tr>
<td>lazyHealthCheckSampleSize</td>
<td>number</td>
<td>The maximum size of the sample of queries to record and consider for the lazyHealthCheckThreshold. Default is 100, which means the result (failure or success) of the last 100 queries will be considered.</td>
</tr>
<tr>
<td>lazyHealthCheckThreshold</td>
<td>number</td>
<td>The threshold, as a percentage, of queries that should fail for the ‘lazy’ health-check to be triggered when healthCheckMode is set to lazy. The default is 20 which means 20% of the last lazyHealthCheckSampleSize queries should fail for a health-check to be triggered.</td>
</tr>
<tr>
<td>lazyHealthCheckUseExponentialBackOff</td>
<td>boolean</td>
<td>Whether the ‘lazy’ health-check should use an exponential back-off instead of a fixed value, between health-check probes. The default is false which means that after a backend has been moved to the ‘down’ state health-check probes are sent every lazyHealthCheckFailedInterval seconds. When set to true, the delay between each probe starts at lazyHealthCheckFailedInterval seconds and double between every probe, capped at lazyHealthCheckMaxBackOff seconds.</td>
</tr>
<tr>
<td>lazyHealthCheckMaxBackOff</td>
<td>number</td>
<td>This value, in seconds, caps the time between two health-check queries when lazyHealthCheckUseExponentialBackOff is set to true. The default is 3600 which means that at most one hour will pass between two health-check queries.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>lazyHealthCheckWhenUpgraded</td>
<td>bool</td>
<td>Whether the auto-upgraded version of this backend (see autoUpgrade) should use the lazy health-checking mode. Default is false, which means it will use the regular health-checking mode.</td>
</tr>
<tr>
<td>ktls</td>
<td>bool</td>
<td>Whether to enable the experimental kernel TLS support on Linux, if both the kernel and the OpenSSL library support it. Default is false. Currently both DoT and DoH backend support this option.</td>
</tr>
<tr>
<td>proxyProtocolAdvertiseTLS</td>
<td>bool</td>
<td>Whether to set the SSL Proxy Protocol TLV in the proxy protocol payload sent to the backend if the query was received over an encrypted channel (DNSCrypt, DoQ, DoH or DoT). Requires useProxyProtocol=true. Default is false.</td>
</tr>
</tbody>
</table>

**getServer** *(index) → Server*

Get a `Server`

**Parameters** or **str index** *(int)* – The number of the server (as seen in `showServers()`) or its UUID as a string.

**Returns** The `Server` object or nil

**getServers()**

Returns a table with all defined servers.

**rmServer(index)**

**rmServer(uuid)**

**rmServer(server)**

Remove a backend server.

**Parameters**

* **or str index** *(int)* – The number of the server (as seen in `showServers()`), its UUID as a string, or a server object.

* **server** *(Server)* – A `Server` object as returned by e.g. `getServer()`.

**Server Functions**

A server object returned by `getServer()` can be manipulated with these functions.

**class Server**

This object represents a backend server. It has several methods.

: **addPool** *(pool)*

Add this server to a pool.

**Parameters** pool *(str)* – The pool to add the server to
: `getLatency()` → double
  New in version 1.6.0.
  Return the average latency of this server over the last 128 UDP queries, in microseconds.

  **Returns** The number of outstanding queries

: `getName()` → string
  Get the name of this server.

  **Returns** The name of the server, or an empty string if it does not have one

: `getNameWithAddr()` → string
  Get the name plus IP address and port of the server

  **Returns** A string containing the server name if any plus the server address and port

: `getDrops()` → int
  New in version 1.6.0.
  Get the number of dropped queries for this server.

  **Returns** The number of dropped queries

: `getOutstanding()` → int
  Get the number of outstanding queries for this server.

  **Returns** The number of outstanding queries

: `isUp()` → bool
  Returns the up status of the server

  **Returns** true when the server is up, false otherwise

: `rmPool(pool)`
  Removes the server from the named pool

  **Parameters** pool (str) – The pool to remove the server from

: `setAuto([status])`
  Set the server in the default auto state. This will enable health check queries that will set the server **up** and **down** appropriately.

  **Parameters** status (bool) – Set the initial status of the server to **up** (true) or **down** (false) instead of using the last known status

: `setDown()`
  Set the server in a **DOWN** state. The server will not receive queries and the health checks are disabled.

: `setLazyAuto([status])`
  New in version 1.8.0.
  Set the server in the ‘lazy’ health-check mode. This will enable health check queries, but only after a configurable threshold of failing regular queries has been reached and only for a short time. See **Healthcheck** for a more detailed explanation.

  **Parameters** status (bool) – Set the initial status of the server to **up** (true) or **down** (false) instead of using the last known status

: `setQPS(limit)`
  Limit the queries per second for this server.

  **Parameters** limit (int) – The maximum number of queries per second

: `setUp()`
  Set the server in an **UP** state. This server will still receive queries and health checks are disabled

Apart from the functions, a **Server** object has these attributes:

**name**
  The name of the server
upStatus
Whether or not this server is up or down

order
The order of the server

weight
The weight of the server

19.1.4 Pools
Servers can be part of any number of pools. Pools are automatically created when a server is added to a pool (with newServer()), or can be manually created with getPool(). Servers that are not assigned to a specific pool get assigned to the default pool that is always present, identified by the empty string "".

getPool(name) → ServerPool
Returns a ServerPool. If the pool does not exist yet, it is created.

Parameters name (string) – The name of the pool

getPoolServers(name) → [ Server ]
Returns a list of Servers or nil.

Parameters name (string) – The name of the pool

getPoolNames() → [ table of names ]
New in version 1.8.0.

Returns a table of all pool names

showPools()
Display the name, associated cache, server policy and associated servers for every pool.

class ServerPool
This represents the pool where zero or more servers are part of.

:getCache () → PacketCache
Returns the PacketCache for this pool or nil.

:getECS ()
Whether dnsdist will add EDNS Client Subnet information to the query before looking up into the cache, when all servers from this pool are down. For more information see ServerPool:setECS().

:setCache (cache)
Adds cache as the pool’s cache.

Parameters cache (PacketCache) – The new cache to add to the pool

:unsetCache ()
Removes the cache from this pool.

:setECS ()
Set to true if dnsdist should add EDNS Client Subnet information to the query before looking up into the cache, when all servers from this pool are down. If at least one server is up, the preference of the selected server is used, this parameter is only useful if all the backends in this pool are down and have EDNS Client Subnet enabled, since the queries in the cache will have been inserted with ECS information. Default is false.

PacketCache
A Pool can have a packet cache to answer queries directly instead of going to the backend. See Caching Responses for a how to.
newPacketCache \( \{ \text{maxEntries}, \; \text{maxTTL=86400}, \; \text{minTTL=0}, \; \text{temporaryFailureTTL=60}, \; \text{staleTTL=60}, \; \text{dontAge=false}, \; \text{numberOfShards=1}, \; \text{deferrableInsertLock=true}, \; \text{maxNegativeTTL=3600}, \; \text{parseECS=false} \} \) → PacketCache

Deprecated since version 1.4.0.

Creates a new PacketCache with the settings specified.

Parameters

- **maxEntries** \((\text{int})\) – The maximum number of entries in this cache
- **maxTTL** \((\text{int})\) – Cap the TTL for records to his number
- **minTTL** \((\text{int})\) – Don’t cache entries with a TTL lower than this
- **temporaryFailureTTL** \((\text{int})\) – On a SERVFAIL or REFUSED from the backend, cache for this amount of seconds
- **staleTTL** \((\text{int})\) – When the backend servers are not reachable, and global configuration setStaleCacheEntriesTTL is set appropriately, TTL that will be used when a stale cache entry is returned
- **dontAge** \((\text{bool})\) – Don’t reduce TTLs when serving from the cache. Use this when dnsdist fronts a cluster of authoritative servers
- **numberOfShards** \((\text{int})\) – Number of shards to divide the cache into, to reduce lock contention
- **deferrableInsertLock** \((\text{bool})\) – Whether the cache should give up insertion if the lock is held by another thread, or simply wait to get the lock.
- **maxNegativeTTL** \((\text{int})\) – Cache a NXDomain or NoData answer from the backend for at most this amount of seconds, even if the TTL of the SOA record is higher
- **parseECS** \((\text{bool})\) – Whether any EDNS Client Subnet option present in the query should be extracted and stored to be able to detect hash collisions involving queries with the same qname, qtype and qclass but a different incoming ECS value. Enabling this option adds a parsing cost and only makes sense if at least one backend might send different responses based on the ECS value, so it’s disabled by default

newPacketCache \( \{ \text{maxEntries}, \; \text{options} \} \) → PacketCache

New in version 1.4.0.

Changed in version 1.6.0: cookieHashing parameter added. numberOfShards now defaults to 20.

Changed in version 1.7.0: skipOptions parameter added.

Changed in version 1.9.0: maximumEntrySize parameter added.

Creates a new PacketCache with the settings specified.

Parameters

- **maxEntries** \((\text{int})\) – The maximum number of entries in this cache

Options:

- **deferrableInsertLock=true** \(\text{bool}\) - Whether the cache should give up insertion if the lock is held by another thread, or simply wait to get the lock.
- **dontAge=false** \(\text{bool}\) - Don’t reduce TTLs when serving from the cache. Use this when dnsdist fronts a cluster of authoritative servers.
- **keeplStaleData=false** \(\text{bool}\) - Whether to suspend the removal of expired entries from the cache when there is no backend available in at least one of the pools using this cache.
- **maxNegativeTTL=3600** \(\text{int}\) - Cache a NXDomain or NoData answer from the backend for at most this amount of seconds, even if the TTL of the SOA record is higher.
- **maxTTL=86400** \(\text{int}\) - Cap the TTL for records to his number.
- **minTTL=0** \(\text{int}\) - Don’t cache entries with a TTL lower than this.
- **numberOfShards=20**: int - Number of shards to divide the cache into, to reduce lock contention. Used to be 1 (no shards) before 1.6.0, and is now 20.
- **parseECS=false**: bool - Whether any EDNS Client Subnet option present in the query should be extracted and stored to be able to detect hash collisions involving queries with the same qname, qtype and qclass but a different incoming ECS value. Enabling this option adds a parsing cost and only makes sense if at least one backend might send different responses based on the ECS value, so it’s disabled by default. Enabling this option is required for the ‘zero scope’ option to work.
- **staleTTL=60**: int - When the backend servers are not reachable, and global configuration `setStaleCacheEntriesTTL` is set appropriately, TTL that will be used when a stale cache entry is returned.
- **temporaryFailureTTL=60**: int - On a SERVFAIL or REFUSED from the backend, cache for this amount of seconds..
- **cookieHashing=false**: bool - If true, EDNS Cookie values will be hashed, resulting in separate entries for different cookies in the packet cache. This is required if the backend is sending answers with EDNS Cookies, otherwise a client might receive an answer with the wrong cookie.
- **skipOptions={}**: Extra list of EDNS option codes to skip when hashing the packet (if cookieHashing above is false, EDNS cookie option number will be added to this list internally).
- **maximumEntrySize=4096**: int - The maximum size, in bytes, of a DNS packet that can be inserted into the packet cache. Default is 4096 bytes, which was the fixed size before 1.9.0, and is also a hard limit for UDP responses.

```java
class PacketCache
    Represents a cache that can be part of ServerPool.

    :dump (fname) - Dump a summary of the cache entries to a file.
        Parameters fname (str) - The path to a file where the cache summary should be dumped.

    :expunge (n) - Remove entries from the cache, leaving at most n entries.
        Parameters n (int) - Number of entries to keep

    :expungeByName (name, qtype=DNSQType.ANY, suffixMatch=false) - Remove entries matching name and type from the cache.
        Changed in version 1.6.0: name can now also be a string.

    :getAddressListByDomain (domain) - New in version 1.8.0.
        This method looks up the answers present in the cache for the supplied domain, and returns the list of addresses present in the answer section of these answers (in A records for IPv4 addresses, and AAAA records for IPv6 ones). The addresses are returned as a list of ComboAddress objects.
        Parameters domain (DNSName) - The domain to look for

    :getDomainListByAddress (addr) - New in version 1.8.0.
        Return a list of domains, as DNSName objects, for which an answer is present in the cache and has a corresponding A record (for IPv4 addresses) or AAAA record (for IPv6 addresses) in the answer section.
```

174 Chapter 19. Reference Guides
Parameters `addr (ComboAddress)` – The address to look for

:getStats ()
New in version 1.4.0.
Return the cache stats (number of entries, hits, misses, deferred lookups, deferred inserts, lookup collisions, insert collisions and TTL too shorts) as a Lua table.

:isFull () → bool
Return true if the cache has reached the maximum number of entries.

:printStats ()
Print the cache stats (number of entries, hits, misses, deferred lookups, deferred inserts, lookup collisions, insert collisions and TTL too shorts).

:purgeExpired (n)
Remove expired entries from the cache until there is at most n entries remaining in the cache.

Parameters `n (int)` – Number of entries to keep

:toString () → string
Return the number of entries in the Packet Cache, and the maximum number of entries

19.1.5 Client State
Also called frontend or bind, the Client State object returned by `getBind()` and listed with `showBinds()` represents an address and port dnsdist is listening on.

:getBind (index) → ClientState
Return a `ClientState` object.

Parameters `index (int)` – The object index

:getBindCount ()
New in version 1.5.0.
Return the number of binds (Do53, DNSCrypt, DoH and DoT).

ClientState functions
class ClientState
This object represents an address and port dnsdist is listening on. When `reuseport` is in use, several ClientState objects can be present for the same address and port.

:attachFilter (filter)
Attach a BPF filter to this frontend.

Parameters `filter (BPFFilter)` – The filter to attach to this frontend

:detachFilter ()
Remove the BPF filter associated to this frontend, if any.

:getEffectiveTLSProvider () → string
New in version 1.7.0.
Return the name of the TLS provider actually used.

:getRequestedTLSProvider () → string
New in version 1.7.0.
Return the name of the TLS provider requested in the configuration.

:getType () → string
New in version 1.7.0.
Return the type of the frontend: UDP, UDP (DNSCrypt), TCP, TCP (DNSCrypt), TCP (DNS over TLS) or TCP (DNS over HTTPS).
toString() → string
Return the address and port this frontend is listening on.

Returns The address and port this frontend is listening on

muted
If set to true, queries received on this frontend will be normally processed and sent to a backend if needed, but no response will be ever be sent to the client over UDP. TCP queries are processed normally and responses sent to the client.

19.1.6 Status, Statistics and More

dumpStats()
Print all statistics dnsdist gathers

getDOHFrontend(idx)
New in version 1.4.0.
Return the DOHFrontend object for the DNS over HTTPS bind of index idx.

getDOHFrontendCount()
New in version 1.5.0.
Return the number of DOHFrontend binds.

g getListOfAddressesOfNetworkInterface(if)
New in version 1.8.0.
Return the list of addresses configured on a given network interface, as strings. This function requires support for getifaddrs, which is known to be present on FreeBSD, Linux, and OpenBSD at least.

Parameters if (str) – The name of the network interface

getListOfNetworkInterfaces()
New in version 1.8.0.
Return the list of network interfaces configured on the system, as strings. This function requires support for getifaddrs, which is known to be present on FreeBSD, Linux, and OpenBSD at least.

g getListOfRangesOfNetworkInterface(if)
New in version 1.8.0.
Return the list of network ranges configured on a given network interface, as strings. This function requires support for getifaddrs, which is known to be present on FreeBSD, Linux, and OpenBSD at least.

Parameters if (str) – The name of the network interface

getMACAddress(ip) → str
New in version 1.8.0.
Return the link-level address (MAC) corresponding to the supplied neighbour IP address, if known by the kernel. The link-level address is returned as a raw binary string. An empty string is returned if no matching entry has been found. This function is only implemented on Linux.

Parameters ip (str) – The IP address, IPv4 or IPv6, to look up the corresponding link-level address for.

getOutgoingTLSSessionCacheSize()
New in version 1.7.0.
Return the number of TLS sessions (for outgoing connections) currently cached.

g getTLSContext(idx)
Return the TLSContext object for the context of index idx.

g getTLSFrontend(idx)
Return the TLSFrontend object for the TLS bind of index idx.
getTLSFrontendCount()
New in version 1.5.0.
Return the number of TLSFrontend binds.

getTopCacheHitResponseRules([top])
New in version 1.6.0.
Return the cache-hit response rules that matched the most.

Parameters:
- **top**(int) – How many response rules to return. Default is 10.

getTopCacheInsertedResponseRules([top])
New in version 1.8.0.
Return the cache-inserted response rules that matched the most.

Parameters:
- **top**(int) – How many response rules to return. Default is 10.

getTopResponseRules([top])
New in version 1.6.0.
Return the response rules that matched the most.

Parameters:
- **top**(int) – How many response rules to return. Default is 10.

getTopRules([top])
New in version 1.6.0.
Return the rules that matched the most.

Parameters:
- **top**(int) – How many rules to return. Default is 10.

getTopSelfAnsweredRules([top])
New in version 1.6.0.
Return the self-answered rules that matched the most.

Parameters:
- **top**(int) – How many rules to return. Default is 10.

grepq(selector, num, options)
grepq(selectors, num, options)
Changed in version 1.9.0: options optional parameter table added.
Prints the last num queries and responses matching selector or selectors. Queries and responses are accounted in separate ring buffers, and answers from the packet cache are not stored in the response ring buffer. Therefore, the num queries and num responses in the output may not always match up.
The selector can be:
- a netmask (e.g. ‘192.0.2.0/24’)
- a DNS name (e.g. ‘dnsdist.org’)
- a response time (e.g. ‘100ms’)

Parameters:
- **selector**(str) – Select queries based on this property.
- **selectors**(str) – A lua table of selectors. Only queries matching all selectors are shown
- **num**(int) – Show a maximum of num recent queries+responses.
- **options**(table) – A table with key: value pairs with options described below.

Options:
- **outputFile=path**: string - Write the output of the command to the supplied file, instead of the standard output.
setStructuredLogging(enable[, options])

New in version 1.9.0.

Set whether log messages should be in a structured-logging-like format. This is turned off by default. The resulting format looks like this (when timestamps are enabled via --log-timestamps and with levelPrefix="prio" and timeFormat="ISO8601"):

```
{ts="2023-11-06T12:04:58+0100" prio="Info" msg="Added downstream server 127.0.0.1:53"}
```

And with levelPrefix="level" and timeFormat="numeric"):

```
{ts="1699268815.133" level="Info" msg="Added downstream server 127.0.0.1:53"}
```

Parameters

- **enable** (*bool*) – Set to true if you want to enable structured logging
- **options** (*table*) – A table with key: value pairs with options described below.

Options:

- **levelPrefix=prefix** (*string*) - Set the prefix for the log level. Default is *prio*.
- **timeFormat=format** (*string*) - Set the time format. Supported values are *ISO8601* and *numeric*. Default is *numeric*.

setVerbose(**verbose**)  

New in version 1.8.0.

Set whether log messages issued at the verbose level should be logged. This is turned off by default.

Parameters **verbose** (*bool*) – Set to true if you want to enable verbose logging

getVerbose()  

New in version 1.8.0.

Get whether log messages issued at the verbose level should be logged. This is turned off by default.

setVerboseHealthChecks(**verbose**)  

Set whether health check errors should be logged. This is turned off by default.

Parameters **verbose** (*bool*) – Set to true if you want to enable health check errors logging

setVerboseLogDestination(**dest**)  

New in version 1.8.0.

Set a destination file to write the ‘verbose’ log messages to, instead of sending them to syslog and/or the standard output which is the default. Note that these messages will no longer be sent to syslog or the standard output once this option has been set. There is no rotation or file size limit. Only use this feature for debugging under active operator control.

Parameters **dest** (*str*) – The destination file

showBinds()  

Print a list of all the current addresses and ports dnsdist is listening on, also called frontends

showDOHFrontends()  

New in version 1.4.0.

Print the list of all available DNS over HTTPS frontends.

showDOH3Frontends()  

New in version 1.9.0.

Print the list of all available DNS over HTTP/3 frontends.
showDOHResponseCodes()  
New in version 1.4.0.  
Print the HTTP response codes statistics for all available DNS over HTTPS frontends.

showDOQFrontends()  
New in version 1.9.0.  
Print the list of all available DNS over QUIC frontends.

showResponseLatency()  
Show a plot of the response time latency distribution

showServers(options)  
Changed in version 1.4.0: options optional parameter added  
This function shows all backend servers currently configured and some statistics. These statics have the following fields:

- # - The number of the server, can be used as the argument for `getServer()`  
- UUID - The UUID of the backend. Can be set with the `id` option of `newServer()`  
- Address - The IP address and port of the server  
- State - The current state of the server  
- Qps - Current number of queries per second  
- Qlim - Configured maximum number of queries per second  
- Ord - The order number of the server  
- Wt - The weight of the server  
- Queries - Total amount of queries sent to this server  
- Drops - Number of queries that were dropped by this server  
- Drate - Number of queries dropped per second by this server  
- Lat - The latency of this server in milliseconds  
- Pools - The pools this server belongs to

Parameters options (table) – A table with key: value pairs with display options.

Options:

- showUUIDs=false: bool - Whether to display the UUIDs, defaults to false.

showTCPStats()  
Show some statistics regarding TCP

showTLSContexts()  
Print the list of all available DNS over TLS contexts.

showTLSErrorCounters()  
New in version 1.4.0.  
Display metrics about TLS handshake failures.

showVersion()  
Print the version of dnsdist

topBandwidth([num])  
Print the top `num` clients that consume the most bandwidth.

Parameters num (int) – Number to show, defaults to 10.
topCacheHitResponseRules ([top[, options]])
New in version 1.6.0.
This function shows the cache-hit response rules that matched the most.

Parameters

- **top** (*int*) – How many rules to show.
- **options** (*table*) – A table with key: value pairs with display options.

Options:

- **showUUIDs=false**: bool - Whether to display the UUIDs, defaults to false.

topCacheInsertedResponseRules ([top[, options]])
New in version 1.8.0.
This function shows the cache-inserted response rules that matched the most.

Parameters

- **top** (*int*) – How many rules to show.
- **options** (*table*) – A table with key: value pairs with display options.

Options:

- **showUUIDs=false**: bool - Whether to display the UUIDs, defaults to false.

topClients ([num])
Print the top num clients sending the most queries over length of ringbuffer.

Parameters **num** (*int*) – Number to show, defaults to 10.

topQueries ([num[, labels]])
Print the num most popular QNAMEs from queries. Optionally grouped by the rightmost labels DNS labels.

Parameters

- **num** (*int*) – Number to show, defaults to 10
- **label** (*int*) – Number of labels to cut down to

topResponses ([num[, rcode[, labels]]])
Print the num most seen responses with an RCODE of rcode. Optionally grouped by the rightmost labels DNS labels.

Parameters

- **num** (*int*) – Number to show, defaults to 10
- **rcode** (*int*) – Response code, defaults to 0 (No Error)
- **label** (*int*) – Number of labels to cut down to

topResponseRules ([top[, options]])
New in version 1.6.0.
This function shows the response rules that matched the most.

Parameters

- **top** (*int*) – How many rules to show.
- **options** (*table*) – A table with key: value pairs with display options.

Options:

- **showUUIDs=false**: bool - Whether to display the UUIDs, defaults to false.
**topRules**([`top`, `options`])

New in version 1.6.0.

This function shows the rules that matched the most.

**Parameters**

- **top** (`int`) – How many rules to show.
- **options** (`table`) – A table with key: value pairs with display options.

**Options:**

- `showUUIDs=false` : bool - Whether to display the UUIDs, defaults to false.

**topSelfAnsweredResponseRules**([`top`, `options`])

New in version 1.6.0.

This function shows the selfanswered response rules that matched the most.

**Parameters**

- **top** (`int`) – How many rules to show.
- **options** (`table`) – A table with key: value pairs with display options.

**Options:**

- `showUUIDs=false` : bool - Whether to display the UUIDs, defaults to false.

**topSlow**([`num`, `limit`, `labels`])

Print the `num` slowest queries that are slower than `limit` milliseconds. Optionally grouped by the rightmost `labels` DNS labels.

**Parameters**

- **num** (`int`) – Number to show, defaults to 10
- **limit** (`int`) – Show queries slower than this amount of milliseconds, defaults to 2000
- **label** (`int`) – Number of labels to cut down to

**19.1.7 Dynamic Blocks**

**addDynamicBlock**(`address`, `message`, `action`, `seconds`, `clientIPMask`, `clientIPPortMask`)

New in version 1.9.0.

Manually block an IP address or range with `message` for (optionally) a number of seconds. The default number of seconds to block for is 10.

**Parameters**

- **address** – A `ComboAddress` or string representing an IPv4 or IPv6 address
- **message** (`string`) – The message to show next to the blocks
- **action** (`int`) – The action to take when the dynamic block matches, see `DNSAction`. (default to `DNSAction.None`, meaning the one set with `setDynBlocksAction()` is used)
- **seconds** (`int`) – The number of seconds this block to expire
- **clientIPMask** (`int`) – The network mask to apply to the address. Default is 32 for IPv4, 128 for IPv6.
- **clientIPPortMask** (`int`) – The port mask to use to specify a range of ports to match, when the clients are behind a CGNAT.

Please see the documentation for `setDynBlocksAction()` to confirm which actions are supported by the action parameter.
addDynBlocks(addresses, message[, seconds=10[, action ]])

Block a set of addresses with message for (optionally) a number of seconds. The default number of seconds to block for is 10. Since 1.3.0, the use of a DynBlockRulesGroup is a much more efficient way of doing the same thing.

Parameters

- **addresses** – set of Addresses as returned by an exceed function
- **message**(string) – The message to show next to the blocks
- **seconds**(int) – The number of seconds this block to expire
- **action**(int) – The action to take when the dynamic block matches, see DNSAction. (default to DNSAction.None, meaning the one set with setDynBlocksAction() is used)

Please see the documentation for setDynBlocksAction() to confirm which actions are supported by the action parameter.

clearDynBlocks()

Remove all current dynamic blocks.

getDynamicBlocks()

New in version 1.9.0.

Return an associative table of active network-based dynamic blocks. The keys are the network IP or range that are blocked, the value are DynBlock objects.

getDynamicBlocksSMT()

New in version 1.9.0.

Return an associative table of active domain-based (Suffix Match Tree or SMT) dynamic blocks. The keys are the domains that are blocked, the values are DynBlock objects.

showDynBlocks()

List all dynamic blocks in effect.

setDynBlocksAction(action)

Set which action is performed when a query is blocked. Only DNSAction.Drop (the default), DNSAction.NoOp, DNSAction.NXDomain, DNSAction.Refused, DNSAction.Truncate and DNSAction.NoRecurse are supported.

setDynBlocksPurgeInterval(sec)

New in version 1.6.0.

Set at which interval, in seconds, the expired dynamic blocks entries will be effectively removed from the tree. Entries are not applied anymore as soon as they expire, but they remain in the tree for a while for performance reasons. Removing them makes the addition of new entries faster and frees up the memory they use. Setting this value to 0 disable the purging mechanism, so entries will remain in the tree.

Parameters **sec**(int) – The interval between two runs of the cleaning algorithm, in seconds.

Default is 60 (1 minute), 0 means disabled.

class DynBlock

New in version 1.9.0.

Represent the current state of a dynamic block.

- **action**
  The action of this block, as an integer representing a DNSAction.

- **blocks**
  The number of queries blocked.

- **bpf**
  Whether this block is using eBPF, as a boolean.
domain
   The domain that is blocked, as a string, for Suffix Match Tree blocks.

reason
   The reason why this block was inserted, as a string.

until
   The time (in seconds since Epoch) at which the block will expire.

warning
   Whether this block is only a warning one (true) or is really enforced (false).

Getting addresses that exceeded parameters

**exceedServFails** (*rate*, *seconds*)
   Get set of addresses that exceed *rate* servfails/s over *seconds* seconds

   Parameters
   • *rate* (*int*) – Number of Servfails per second to exceed
   • *seconds* (*int*) – Number of seconds the rate has been exceeded

**exceedNXDOMAINs** (*rate*, *seconds*)
   get set of addresses that exceed *rate* NXDOMAIN/s over *seconds* seconds

   Parameters
   • *rate* (*int*) – Number of NXDOMAIN per second to exceed
   • *seconds* (*int*) – Number of seconds the rate has been exceeded

**exceedRespByteRate** (*rate*, *seconds*)
   get set of addresses that exceeded *rate* bytes/s answers over *seconds* seconds

   Parameters
   • *rate* (*int*) – Number of bytes per second to exceed
   • *seconds* (*int*) – Number of seconds the rate has been exceeded

**exceedQRate** (*rate*, *seconds*)
   Get set of address that exceed *rate* queries/s over *seconds* seconds

   Parameters
   • *rate* (*int*) – Number of queries per second to exceed
   • *seconds* (*int*) – Number of seconds the rate has been exceeded

**exceedQTypeRate** (*type*, *rate*, *seconds*)
   Get set of address that exceed *rate* queries/s for queries of QType *type* over *seconds* seconds

   Parameters
   • *type* (*int*) – QType
   • *rate* (*int*) – Number of QType queries per second to exceed
   • *seconds* (*int*) – Number of seconds the rate has been exceeded

DynBlockRulesGroup

Instead of using several `exceed*()` lines, dnssdist 1.3.0 introduced a new *DynBlockRulesGroup* object which can be used to group dynamic block rules.

See *Dynamic Rule Generation* for more information about the case where using a *DynBlockRulesGroup* might be faster than the existing rules.
**dnsdist**

**dynBlockRulesGroup()** → DynBlockRulesGroup

Creates a new `DynBlockRulesGroup` object.

**class DynBlockRulesGroup**

Represents a group of dynamic block rules.

```python
:setCacheMissRatio(ratio, seconds, reason, blockingTime, minimumNumberOfResponses, minimumGlobalCacheHitRatio, action, warningRate)
```

New in version 1.9.0.

Adds a rate-limiting rule for the ratio of cache-misses responses over the total number of responses for a given client. A minimum global cache-hit ratio has to be specified to prevent false-positive when the cache is empty.

**Parameters**

- `ratio (float)` – Ratio of cache-miss responses per second over the total number of responses for this client to exceed
- `seconds (int)` – Number of seconds the ratio has been exceeded
- `reason (string)` – The message to show next to the blocks
- `blockingTime (int)` – The number of seconds this block to expire
- `minimumNumberOfResponses (int)` – How many total responses is required for this rule to apply
- `minimumGlobalCacheHitRatio (float)` – The minimum global cache-hit ratio (over all pools, so cache-hits / (cache-hits + cache-misses)) for that rule to be applied.
- `action (int)` – The action to take when the dynamic block matches, see `DNSAction`.
  (default to the one set with `setDynBlocksAction()`)
- `warningRatio (float)` – If set to a non-zero value, the ratio above which a warning message will be issued and a no-op block inserted

```python
:setMasks(v4, v6, port)
```

New in version 1.7.0.

Set the number of bits to keep in the IP address when inserting a block. The default is 32 for IPv4 and 128 for IPv6, meaning that only the exact address is blocked, but in some scenarios it might make sense to block a whole /64 IPv6 range instead of a single address, for example. It is also possible to take the IPv4 UDP and TCP ports into account, for CGNAT deployments, by setting the number of bits of the port to consider. For example passing 2 as the last parameter, which only makes sense if the previous parameters are respectively 32 and 128, will split a given IP address into four port ranges: 0-16383, 16384-32767, 32768-49151 and 49152-65535.

**Parameters**

- `v4 (int)` – Number of bits to keep for IPv4 addresses. Default is 32
- `v6 (int)` – Number of bits to keep for IPv6 addresses. Default is 128
- `port (int)` – Number of bits of port to consider over IPv4. Default is 0 meaning that the port is not taken into account

```python
:setQueryRate(rate, seconds, reason, blockingTime, action, warningRate)
```

Adds a query rate-limiting rule, equivalent to: `addDynBlocks(exceedQRate(rate, seconds), reason, blockingTime, action)`

**Parameters**

- `rate (int)` – Number of queries per second to exceed
- `seconds (int)` – Number of seconds the rate has been exceeded
- `reason (string)` – The message to show next to the blocks
• **blockingTime** (*int*) – The number of seconds this block to expire

• **action** (*int*) – The action to take when the dynamic block matches, see `DNSAction`, (default to the one set with `setDynBlocksAction()`)

• **warningRate** (*int*) – If set to a non-zero value, the rate above which a warning message will be issued and a no-op block inserted

: **setNewBlockInsertedHook** (*hook*)

    New in version 1.9.0.

Set a Lua function that will be called everytime a new dynamic block is inserted. The function receives:

• an integer whose value is 0 if the block is Netmask-based one (Client IP or range) and 1 instead (Domain name suffix)

• the key (Client IP/range or domain suffix) as a string

• the reason of the block as a string

• the action of the block as an integer

• the duration of the block in seconds

• whether this is a warning block (true) or not (false)

: **setRCodeRate** (*rcode, rate, seconds, reason, blockingTime, action, warningRate*)

    New in version 1.5.0.

    Adds a rate-limiting rule for responses of code *rcode*, equivalent to: `addDynBlocks(exceedServfails(rcode, rate, seconds), reason, blockingTime, action)`

    **Parameters**

    • **rcode** (*int*) – The response code

    • **rate** (*int*) – Number of responses per second to exceed

    • **seconds** (*int*) – Number of seconds the rate has been exceeded

    • **reason** (*string*) – The message to show next to the blocks

    • **blockingTime** (*int*) – The number of seconds this block to expire

    • **action** (*int*) – The action to take when the dynamic block matches, see `DNSAction`, (default to the one set with `setDynBlocksAction()`)

    • **warningRate** (*int*) – If set to a non-zero value, the rate above which a warning message will be issued and a no-op block inserted

: **setRCodeRatio** (*rcode, ratio, seconds, reason, blockingTime, minimumNumberOfResponses, action, warningRate*)

    New in version 1.5.0.

    Adds a rate-limiting rule for the ratio of responses of code *rcode* over the total number of responses for a given client.

    **Parameters**

    • **rcode** (*int*) – The response code

    • **ratio** (*float*) – Ratio of responses per second of the given rcode over the total number of responses for this client to exceed

    • **seconds** (*int*) – Number of seconds the ratio has been exceeded

    • **reason** (*string*) – The message to show next to the blocks

    • **blockingTime** (*int*) – The number of seconds this block to expire

    • **minimumNumberOfResponses** (*int*) – How many total responses is required for this rule to apply
• **action** *(int)* – The action to take when the dynamic block matches, see **DNSAction**. (default to the one set with [setDynBlocksAction()](#))

• **warningRatio** *(float)* – If set to a non-zero value, the ratio above which a warning message will be issued and a no-op block inserted

: **setQTypeRate** *(qtype, rate, seconds, reason, blockingTime[, action[, warningRate ]])**

Adds a rate-limiting rule for queries of type *qtype*, equivalent to:

```
addDynBlocks(exceedQTypeRate(type, rate, seconds), reason, blockingTime, action)
```

**Parameters**

- **qtype** *(int)* – The *qtype*
- **rate** *(int)* – Number of queries per second to exceed
- **seconds** *(int)* – Number of seconds the rate has been exceeded
- **reason** *(string)* – The message to show next to the blocks
- **blockingTime** *(int)* – The number of seconds this block to expire

• **action** *(int)* – The action to take when the dynamic block matches, see **DNSAction**. (default to the one set with [setDynBlocksAction()](#))

• **warningRate** *(int)* – If set to a non-zero value, the rate above which a warning message will be issued and a no-op block inserted

: **setResponseByteRate** *(rate, seconds, reason, blockingTime[, action[, warningRate ]])**

Adds a bandwidth rate-limiting rule for responses, equivalent to:

```
addDynBlocks(exceedRespByteRate(rate, seconds), reason, blockingTime, action)
```

**Parameters**

- **rate** *(int)* – Number of bytes per second to exceed
- **seconds** *(int)* – Number of seconds the rate has been exceeded
- **reason** *(string)* – The message to show next to the blocks
- **blockingTime** *(int)* – The number of seconds this block to expire

• **action** *(int)* – The action to take when the dynamic block matches, see **DNSAction**. (default to the one set with [setDynBlocksAction()](#))

• **warningRate** *(int)* – If set to a non-zero value, the rate above which a warning message will be issued and a no-op block inserted

: **setSuffixMatchRule** *(seconds, reason, blockingTime, action, visitor)*

New in version 1.4.0.

Changed in version 1.7.0: This visitor function can now optionally return an additional string which will be set as the *reason* for the dynamic block.

Changed in version 1.9.0: This visitor function can now optionally return an additional integer which will be set as the *action* for the dynamic block.

Set a Lua visitor function that will be called for each label of every domain seen in queries and responses. The function receives a *StatNode* object representing the stats of the parent, a *StatNodeStats* one with the stats of the current label and a second *StatNodeStats* with the stats of the current node plus all its children. Note that this function will not be called if a FFI version has been set using [DynBlockRulesGroup:setSuffixMatchRuleFFI()](#). If the function returns true, the current label will be blocked according to the *seconds*, *reason*, *blockingTime* and *action* parameters. Since 1.7.0, the function can return an additional string, in addition to the boolean, which will be set as the *reason* for the dynamic block. Selected domains can be excluded from this processing using the [DynBlockRulesGroup:excludeDomains()](#) method.

This replaces the existing [addDynBlockSMT()](#) function.
Parameters

- **seconds** (*int*) – Number of seconds the rate has been exceeded
- **reason** (*string*) – The message to show next to the blocks
- **blockingTime** (*int*) – The number of seconds this block to expire
- **action** (*int*) – The action to take when the dynamic block matches, see `DNSAction`.
  (default to the one set with `setDynBlocksAction()`)
- **visitor** (*function*) – The Lua function to call.

::setSuffixMatchRuleFFI (seconds, reason, blockingTime, action, visitor)

New in version 1.4.0.

Set a Lua FFI visitor function that will be called for each label of every domain seen in queries and responses. The function receives a `dnsdist_fii_stat_node_t` object containing the stats of the parent, a second one with the stats of the current label and one with the stats of the current node plus all its children. If the function returns true, the current label will be blocked according to the `seconds`, `reason`, `blockingTime` and `action` parameters. Selected domains can be excluded from this processing using the `DynBlockRulesGroup:excludeDomains()` method.

Parameters

- **seconds** (*int*) – Number of seconds the rate has been exceeded
- **reason** (*string*) – The message to show next to the blocks
- **blockingTime** (*int*) – The number of seconds this block to expire
- **action** (*int*) – The action to take when the dynamic block matches, see `DNSAction`.
  (default to the one set with `setDynBlocksAction()`)
- **visitor** (*function*) – The Lua FFI function to call.

::apply()

Walk the in-memory query and response ring buffers and apply the configured rate-limiting rules, adding dynamic blocks when the limits have been exceeded.

::setQuiet (quiet)

New in version 1.4.0.

Set whether newly blocked clients or domains should be logged.

Parameters **quiet** (*bool*) – True means that insertions will not be logged, false that they will. Default is false.

::excludeDomains (domains)

New in version 1.4.0.

Exclude this domain, or list of domains, meaning that no dynamic block will ever be inserted for this domain via `DynBlockRulesGroup:setSuffixMatchRule()` or `DynBlockRulesGroup:setSuffixMatchRuleFFI()`. Default to empty, meaning rules are applied to all domains.

Parameters **domain** (*str*) – A domain, or list of domains, as strings, like for example “powerdns.com”

::excludeRange (netmasks)

Changed in version 1.6.0: This method now accepts a `NetmaskGroup` object.

Exclude this range, or list of ranges, meaning that no dynamic block will ever be inserted for clients in that range. Default to empty, meaning rules are applied to all ranges. When used in combination with `DynBlockRulesGroup:includeRange()`, the more specific entry wins.

Parameters **netmasks** (*list*) – A `NetmaskGroup` object, or a netmask or list of netmasks as strings, like for example “192.0.2.1/24”
:includeRange (netmasks)
   Changed in version 1.6.0: This method now accepts a `NetmaskGroup` object.
   Include this range, or list of ranges, meaning that rules will be applied to this range. When used in combination with `DynBlockRulesGroup:excludeRange()`, the more specific entry wins.
   Parameters netmasks (list) – A `NetmaskGroup` object, or a netmask or list of netmasks as strings, like for example “192.0.2.1/24”

:removeRange (netmasks)
   New in version 1.8.3.
   Remove a previously included or excluded range. The range should be an exact match of the existing entry to remove.
   Parameters netmasks (list) – A `NetmaskGroup` object, or a netmask or list of netmasks as strings, like for example “192.0.2.1/24”

:toString ()
   Return a string describing the rules and range exclusions of this DynBlockRulesGroup.

StatNode

class StatNode
   Represent a given node, for the visitor functions used with `DynBlockRulesGroup:setSuffixMatchRule()` and `DynBlockRulesGroup:setSuffixMatchRuleFFI()`.
   fullname
      The complete name of that node, ie ‘www.powerdns.com.’.
   labelsCount
      The number of labels in that node, for example 3 for ‘www.powerdns.com’.
   :numChildren ()
      The number of children of that node.

class StatNodeStats
   Represent the metrics for a given node, for the visitor functions used with `DynBlockRulesGroup:setSuffixMatchRule()` and `DynBlockRulesGroup:setSuffixMatchRuleFFI()`.
   bytes
      The number of bytes for all responses returned for that node.
   drops
      The number of drops for that node.
   noerrors
      The number of No Error answers returned for that node.
   hits
      New in version 1.8.0.
      The number of cache hits for that node.
   nxdomains
      The number of NXDomain answers returned for that node.
   queries
      The number of queries for that node.
   servfails
      The number of Server Failure answers returned for that node.
**SuffixMatchNode**

A SuffixMatchNode can be used to quickly check whether a given name belongs to a set or not. This is achieved using an efficient tree structure based on DNS labels, making lookups cheap. Be careful that Suffix Node matching will match for any sub-domain, regardless of the depth, under the name added to the set. For example, if ‘example.com.’ is added to the set, ‘www.example.com.’ and ‘sub.www.example.com.’ will match as well. If you are looking for exact name matching, your might want to consider using a DNSNameSet instead.

```python
newSuffixMatchNode()
```

Creates a new `SuffixMatchNode`.

class SuffixMatchNode
Represents a set of DNS suffixes for quick matching.

: `add(name)`
Changed in version 1.4.0: This method now accepts strings, lists of DNSNames and lists of strings.

Add a suffix to the current set.

Parameters
- `name` (table) – The suffix to add to the set.
- `name` – The suffix to add to the set.
- `name` – The suffixes to add to the set. Elements of the table should be of the same type, either DNSName or string.

: `check(name)` → bool
Return true if the given name is a sub-domain of one of those in the set, and false otherwise.

Parameters `name` (DNSName) – The name to test against the set.

: `getBestMatch(name)` → DNSName
New in version 1.8.0.

Returns the best match for the supplied name, or nil if there was no match.

Parameters `name` (DNSName) – The name to look up.

: `remove(name)`
New in version 1.5.0.

Remove a suffix from the current set.

Parameters
- `name` (table) – The suffix to remove from the set.
- `name` – The suffix to remove from the set.
- `name` – The suffixes to remove from the set. Elements of the table should be of the same type, either DNSName or string.

19.1.8 Outgoing TLS tickets cache management

Since 1.7, dnsdist supports securing the connection toward backends using DNS over TLS. For these connections, it keeps a cache of TLS tickets to be able to resume a TLS session quickly. By default that cache contains up to 20 TLS tickets per-backend, is cleaned up every 60s, and TLS tickets expire if they have not been used after 600 seconds. These values can be set at configuration time via:

```python
setOutgoingTLSSessionsCacheMaxTicketsPerBackend(num)
```

Set the maximum number of TLS tickets to keep, per-backend, to be able to quickly resume outgoing TLS connections to a backend. Keeping more tickets might provide a better TLS session resumption rate if there is a sudden peak of outgoing connections, at the cost of using a bit more memory.

Parameters `num` (int) – The number of TLS tickets to keep, per-backend. The default is 20.
setOutgoingTLSSessionsCacheCleanupDelay \((delay)\)
Set the number of seconds between two scans of the TLS sessions cache, removing expired tickets and freeing up memory. Decreasing that value will lead to more scans, freeing up memory more quickly but using a bit more CPU doing so.

Parameters delay \((int)\) – The number of seconds between two scans of the cache. The default is 60.

setOutgoingTLSSessionsCacheMaxTicketValidity \((validity)\)
Set the number of seconds that a given TLS ticket can be kept inactive in the TLS sessions cache. After that delay the ticket will be removed during the next cleanup of the cache. Increasing that value might increase the TLS resumption rate if new connections are not often created, but it might also lead to trying to reuse a ticket that the server will consider too old and refuse.

Parameters validity \((int)\) – The number of seconds a ticket is considered valid. The default is 600, which matches the default lifetime of TLS tickets set by OpenSSL.

19.1.9 Other functions

getAddressInfo \((hostname, callback)\)
New in version 1.9.0.
Asynchronously resolve, via the system resolver (using getaddrinfo()), the supplied hostname to IPv4 and IPv6 addresses (if configured on the host) before invoking the supplied callback function with the hostname and a list of IPv4 and IPv6 addresses as ComboAddress. For example, to get the addresses of Quad9’s resolver and dynamically add them as backends:

```lua
function resolveCB(hostname, ips)
    for _, ip in ipairs(ips) do
        newServer(ip:toString())
    end
end
getAddressInfo('dns.quad9.net.', resolveCB)
```

Parameters
- hostname \((str)\) – The hostname to resolve.
- callback \((function)\) – The function to invoke when the name has been resolved.

ggetCurrentTime \(\rightarrow\) timespec
New in version 1.8.0.
Return the current time, in whole seconds and nanoseconds since epoch.

Returns A timespec object, see timespec
ggetResolvers \((path)\)
New in version 1.8.0.
This function can be used to get a Lua table of name servers from a file in the resolv.conf format.

Parameters path \((str)\) – The path to the file, usually /etc/resolv.conf
ggetStatisticsCounters ()
This function returns a Lua associative array of metrics, with the metric name as key and the current value of the counter as value.
maintenance ()
If this function exists, it is called every second to do regular tasks. This can be used for e.g. Dynamic Blocks.
threadmessage \((cmd, dict)\)
New in version 1.8.0.
This function, if it exists, is called when a separate thread (made with \texttt{newThread()}) calls \texttt{submitToMainThread()}.

\begin{verbatim}
newThread (code)
\end{verbatim}
New in version 1.8.0.
Spawns a separate thread running the supplied code. Code is supplied as a string, not as a function object. Note that this function does nothing in ‘client’ or ‘config-check’ modes.

\begin{verbatim}
submitToMainThread (cmd, dict)
\end{verbatim}
New in version 1.8.0.
Must be called from a separate thread (made with \texttt{newThread()}), submits data to the main thread by calling \texttt{threadmessage()} in it. If no \texttt{threadmessage} receiver is present in the main thread, \texttt{submitToMainThread} logs an error but returns normally.

The \texttt{cmd} argument is a string. The \texttt{dict} argument is a Lua table.

\begin{verbatim}
setAllowEmptyResponse ()
\end{verbatim}
New in version 1.4.0.
Set to true (defaults to false) to allow empty responses (qdcount=0) with a NoError or NXDomain rcode (default) from backends. dnsdist drops these responses by default because it can’t match them against the initial query since they don’t contain the qname, qtype and qclass, and therefore the risk of collision is much higher than with regular responses.

\begin{verbatim}
setDropEmptyQueries (drop)
\end{verbatim}
New in version 1.6.0.
Set to true (defaults to false) to drop empty queries (qdcount=0) right away, instead of answering with a NotImp rcode. dnsdist used to drop these queries by default because most rules and existing Lua code expects a query to have a qname, qtype and qclass. However \texttt{RFC 7873} uses these queries to request a server cookie, and \texttt{RFC 8906} as a conformance test, so answering these queries with NotImp is much better than not answering at all.

\begin{verbatim}
Parameters drop (bool) – Whether to drop these queries (defaults to false)
\end{verbatim}

\begin{verbatim}
setProxyProtocolMaximumPayloadSize (size)
\end{verbatim}
New in version 1.6.0.
Set the maximum size of a Proxy Protocol payload that dnsdist is willing to accept, in bytes. The default is 512, which is more than enough except for very large TLV data. This setting can’t be set to a value lower than 16 since it would deny of Proxy Protocol headers.

\begin{verbatim}
Parameters size (int) – The maximum size in bytes (default is 512)
\end{verbatim}

\begin{verbatim}
setTCPFastOpenKey (key)
\end{verbatim}
New in version 1.8.0.
Set the supplied TCP Fast Open key on all frontends. This can for example be used to allow all dnsdist instances in an anycast cluster to use the same TCP Fast Open key, reducing round-trips.

\begin{verbatim}
Parameters key (string) – The format of the key can be found in /proc/sys/net/ipv4/tcp_fastopen_key
\end{verbatim}

\begin{verbatim}
makeIPCipherKey (password) → string
\end{verbatim}
New in version 1.4.0.
Hashes the password to generate a 16-byte key that can be used to pseudonymize IP addresses with IP cipher.

\begin{verbatim}
generateOCSPResponse (pathToServerCertificate, pathToCACertificate, pathToCAPrivateKey, outputFile, numberOfDaysOfValidity, numberOfMinutesOfValidity)
\end{verbatim}
New in version 1.4.0.
When a local PKI is used to issue the certificate, or for testing purposes, \texttt{generateOCSPResponse()} can be used to generate an OCSP response file for a certificate, using the certificate and private key of
the certification authority that signed that certificate. The resulting file can be directly used with the 
addDOHLocal() or the addTLSLocal() functions.

Parameters

- **pathToServerCertificate** *(string)* – Path to a file containing the certificate used by the server.

- **pathToCACertificate** *(string)* – Path to a file containing the certificate of the certification authority that was used to sign the server certificate.

- **pathToCAPrivateKey** *(string)* – Path to a file containing the private key corresponding to the certification authority certificate.

- **outputFile** *(string)* – Path to a file where the resulting OCSP response will be written to.

- **numberOfDaysOfValidity** *(int)* – Number of days this OCSP response should be valid.

- **numberOfMinutesOfValidity** *(int)* – Number of minutes this OCSP response should be valid, in addition to the number of days.

getRingEntries()

New in version 1.8.0.

Return a list of all the entries, queries and responses alike, that are present in the in-memory ring buffers, as 
LuaRingEntry objects.

loadTLSEngine *(engineName[, defaultString]*)

New in version 1.8.0.

Load the OpenSSL engine named engineName, setting the engine default string to defaultString if supplied. Engines can be used to accelerate cryptographic operations, like for example Intel QAT. At the moment up to a maximum of 32 loaded engines are supported, and that support is experimental. Some engines might actually degrade performance unless the TLS asynchronous mode of OpenSSL is enabled. To enable it see the tlsAsyncMode parameter on addTLSLocal().

Parameters

- **engineName** *(string)* – The name of the engine to load.

- **defaultString** *(string)* – The default string to pass to the engine. The exact value depends on the engine but represents the algorithms to register with the engine, as a list of comma-separated keywords. For example “RSA,EC,DSA,DH,PKEY,PKEY_CRYPTO,PKEY ASN1”.

loadTLSProvider *(providerName)*

New in version 1.8.0.

Load the OpenSSL provider named providerName. Providers can be used to accelerate cryptographic operations, like for example Intel QAT. At the moment up to a maximum of 32 loaded providers are supported, and that support is experimental. Note that loadTLSProvider() is only available when building against OpenSSL version >= 3.0 and with the --enable-tls-provider configure flag on. In other cases, loadTLSEngine() should be used instead. Some providers might actually degrade performance unless the TLS asynchronous mode of OpenSSL is enabled. To enable it see the tlsAsyncMode parameter on addTLSLocal().

Parameters

- **providerName** *(string)* – The name of the provider to load.

newTLSCertificate *(pathToCert[, options]*)

New in version 1.8.0.

Creates a TLSCertificate object suited to be used with functions like addDOHLocal() and addTLSLocal() for TLS certificate configuration.

PKCS12 files are only supported by the openssl provider, password-protected or not.

Parameters
**pathToCert** *(string)* – Path to a file containing the certificate or a PKCS12 file containing both a certificate and a key.

**options** *(table)* – A table with key: value pairs with additional options.

Options:

- `key="path/to/key"`: string - Path to a file containing the key corresponding to the certificate.
- `password="pass"`: string - Password protecting the PKCS12 file if appropriate.

```python
def newTLS妾ertificate("path/to/pub.crt", {key="path/to/private.pem"})
def newTLS妾ertificate("path/to/domain.p12", {password="passphrase"}) -- use a password protected PKCS12 file
```

### DOHFrontend

class DOHFrontend

New in version 1.4.0.

This object represents an address and port dnsdist is listening on for DNS over HTTPS queries.

: `getAddressAndPort()` → `string`

New in version 1.7.1.

Return the address and port this frontend is listening on.

: `loadNewCertificatesAndKeys(certFile(s), keyFile(s))`

New in version 1.6.1.

Changed in version 1.8.0: `certFile` now accepts a TLSCertificate object or a list of such objects (see `newTLS妾ertificate()`)  

Parameters

- `certFile(s) (str)` – The path to a X.509 certificate file in PEM format, a list of paths to such files, or a TLSCertificate object.
- `keyFile(s) (str)` – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the `certFile(s)` ones. Ignored if `certFile` contains TLSCertificate objects.

: `loadTicketsKeys(ticketsKeysFile)`

Load new tickets keys from the selected file, replacing the existing ones. These keys should be rotated often and never written to persistent storage to preserve forward secrecy. The default is to generate a random key. dnsdist supports several tickets keys to be able to decrypt existing sessions after the rotation. See *[TLS Sessions Management]* for more information.

Parameters `ticketsKeysFile (str)` – The path to a file from where TLS tickets keys should be loaded.

: `reloadCertificates()`  

Reload the current TLS certificate and key pairs.

: `rotateTicketsKey()`  

Replace the current TLS tickets key by a new random one.

: `setResponsesMap(rules)`

Set a list of HTTP response rules allowing to intercept HTTP queries very early, before the DNS payload has been processed, and send custom responses including error pages, redirects and static content.

Parameters of `DOHResponseMapEntry objects rules (list)` – A list of `DOHResponseMapEntry` objects, obtained with `newDOHResponseMapEntry()`.

---

19.1. Configuration Reference
newDOHResponseMapEntry \( (regex, status, content[, headers]) \) → DOHResponseMapEntry

New in version 1.4.0.

Return a DOHResponseMapEntry that can be used with \texttt{DOHFrontend:setResponsesMap()}. Every query whose path is listed in the \texttt{urls} parameter to \texttt{addDOHLocal()} and matches the regular expression supplied in \texttt{regex} will be immediately answered with a HTTP response. The status of the HTTP response will be the one supplied by \texttt{status}, and the content set to the one supplied by \texttt{content}, except if the status is a redirection (3xx) in which case the content is expected to be the URL to redirect to.

**Parameters**

- \texttt{regex (str)} – A regular expression to match the path against.
- \texttt{status (int)} – The HTTP code to answer with.
- \texttt{content (str)} – The content of the HTTP response, or a URL if the status is a redirection (3xx).
- \texttt{of headers (table)} – The custom headers to set for the HTTP response, if any. The default is to use the value of the \texttt{customResponseHeaders} parameter passed to \texttt{addDOHLocal()}.

\textbf{LuaRingEntry}

\texttt{class LuaRingEntry}

New in version 1.8.0.

This object represents an entry from the in-memory ring buffers, query or response.

\texttt{backend}

If this entry is a response, the backend from which it has been received as a \texttt{ComboAddress}.

\texttt{LuaRingEntry.dnsheader}

The \texttt{DNSHeader (dh) object} of this entry.

\texttt{isResponse}

Whether this entry is a response (true) or a request (false).

\texttt{macAddress}

The MAC address of the client as a string, if available.

\texttt{protocol}

The protocol (Do53 UDP, Do53 TCP, DoT, DoH, …) over which this entry was received, as a string.

\texttt{qname}

The qname of this entry as a \texttt{DNSName objects}.

\texttt{qtype}

The qtype of this entry as an integer.

\texttt{requestor}

The requestor (client IP) of this entry as a \texttt{ComboAddress}.

\texttt{size}

The size of the DNS payload of that entry, in bytes.

\texttt{LuaRingEntry.usec}

The response time (elapsed time between the request was received and the response sent) in milliseconds.

\texttt{LuaRingEntry.when}

The timestamp of this entry, as a \texttt{timespec}.
**timespec**

```python
class timespec
```
New in version 1.8.0.

This object represents a timestamp in the timespec format.

```
tv_sec
   Number of seconds elapsed since Unix epoch.
```

```
tv_nsec
   Number of remaining nanoseconds elapsed since Unix epoch after subtracting the seconds from the tv_sec field.
```

**TLSContext**

```python
class TLSContext
```
This object represents an address and port dnsdist is listening on for DNS over TLS queries.

```python
:loadTicketsKeys(ticketsKeysFile)
```
Load new tickets keys from the selected file, replacing the existing ones. These keys should be rotated often and never written to persistent storage to preserve forward secrecy. The default is to generate a random key. The OpenSSL provider supports several tickets keys to be able to decrypt existing sessions after the rotation, while the GnuTLS provider only supports one key. See [TLS Sessions Management](#) for more information.

**Parameters**

- `ticketsKeysFile (str)` – The path to a file from where TLS tickets keys should be loaded.

```python
:rotateTicketsKey()
```
Replace the current TLS tickets key by a new random one.

**TLSFrontend**

```python
class TLSFrontend
```
This object represents the configuration of a listening frontend for DNS over TLS queries. To each frontend is associated a TLSContext.

```python
:getAddressAndPort () → string
```
New in version 1.7.1.

Return the address and port this frontend is listening on.

```python
:loadNewCertificatesAndKeys(certFile(s), keyFile(s))
```
Create and switch to a new TLS context using the same options than were passed to the corresponding `addTLSLocal()` directive, but loading new certificates and keys from the selected files, replacing the existing ones.

**Parameters**

- `certFile(s) (str)` – The path to a X.509 certificate file in PEM format, or a list of paths to such files.
- `keyFile(s) (str)` – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the certFile(s) ones.

```python
:loadTicketsKeys(ticketsKeysFile)
```
New in version 1.6.0: Load new tickets keys from the selected file, replacing the existing ones. These keys should be rotated often and never written to persistent storage to preserve forward secrecy. The default is to generate a random key. The OpenSSL provider supports several tickets keys.
keys to be able to decrypt existing sessions after the rotation, while the GnuTLS provider only supports one key. See *TLS Sessions Management* for more information.

**param str ticketsKeysFile**  The path to a file from where TLS tickets keys should be loaded.

):(reloadCertificates())
New in version 1.6.0: Reload the current TLS certificate and key pairs.

):(rotateTicketsKey())
New in version 1.6.0: Replace the current TLS tickets key by a new random one.

**EDNS on Self-generated answers**

There are several mechanisms in dnsdist that turn an existing query into an answer right away, without reaching out to the backend, including `SpoofAction()`, `RCodeAction()`, `TCAction()` and returning a response from Lua. Those responses should, according to RFC 6891, contain an OPT record if the received request had one, which is the case by default and can be disabled using `setAddEDNSToSelfGeneratedResponses()`.

We must, however, provide a responder’s maximum payload size in this record, and we can’t easily know the maximum payload size of the actual backend so we need to provide one. The default value is 1232 since 1.6.0, and can be overridden using `setPayloadSizeOnSelfGeneratedAnswers()`.

**setAddEDNSToSelfGeneratedResponses** *(add)*

Whether to add EDNS to self-generated responses, provided that the initial query had EDNS.

- **Parameters**
  - **add** *(bool)* – Whether to add EDNS, default is true.

**setPayloadSizeOnSelfGeneratedAnswers** *(payloadSize)*

Changed in version 1.6.0: Default value changed from 1500 to 1232.

Set the UDP payload size advertised via EDNS on self-generated responses. In accordance with RFC 6891, values lower than 512 will be treated as equal to 512.

- **Parameters**
  - **payloadSize** *(int)* – The responder’s maximum UDP payload size, in bytes.
    Default is 1232 since 1.6.0, it was 1500 before.

**Security Polling**

PowerDNS products can poll the security status of their respective versions. This polling, naturally, happens over DNS. If the result is that a given version has a security problem, the software will report this at level ‘Error’ during startup, and repeatedly during operations, every `setSecurityPollInterval()` seconds.

By default, security polling happens on the domain ‘secpoll.powerdns.com’, but this can be changed with the `setSecurityPollSuffix()` function. If this setting is made empty, no polling will take place. Organizations wanting to host their own security zones can do so by changing this setting to a domain name under their control.

To enable distributors of PowerDNS to signal that they have backported versions, the PACKAGEVERSION compilation-time macro can be used to set a distributor suffix.

**setSecurityPollInterval** *(interval)*

Set the interval, in seconds, between two security polls.

- **Parameters**
  - **interval** *(int)* – The interval, in seconds, between two polls. Default is 3600.

**setSecurityPollSuffix** *(suffix)*

Domain name from which to query security update notifications. Setting this to an empty string disables secpoll.

- **Parameters**
  - **suffix** *(string)* – The suffix to use, default is ‘secpoll.powerdns.com’.
19.2 Constants

There are many constants in dnsdist.

19.2.1 OpCode

These constants represent the OpCode of a query.

- DNSOpcode.Query
- DNSOpcode.IQuery
- DNSOpcode.Status
- DNSOpcode.Notify
- DNSOpcode.Update

19.2.2 DNSClass

These constants represent the CLASS of a DNS record.

- DNSClass.IN
- DNSClass.CHAOS
- DNSClass.NONE
- DNSClass.ANY

19.2.3 RCode

These constants represent the different RCODEs for DNS messages.

Changed in version 1.4.0: The prefix is changed from dnsdist to DNSRCode.

Changed in version 1.7.0: The lookup fallback from dnsdist to DNSRCode was removed.

- DNSRCode.NOERROR
- DNSRCode.FORMERR
- DNSRCode.SERVFAIL
- DNSRCode.NXDOMAIN
- DNSRCode.NOTIMP
- DNSRCode.REFUSED
- DNSRCode.YXDOMAIN
- DNSRCode.YXRRSET
- DNSRCode.NXRRSET
- DNSRCode.NOTAUTH
- DNSRCode.NOTZONE

RCodes below are extended RCodes that can only be matched using ERCodeRule().

- DNSRCode.BADVERS
• DNSRCode.BADSIG
• DNSRCode.BADKEY
• DNSRCode.BADTIME
• DNSRCode.BADMODE
• DNSRCode.BADNAME
• DNSRCode.BADALG
• DNSRCode.BADTRUNC
• DNSRCode.BADCOOKIE

19.2.4 EDNSOptionCode

• EDNSOptionCode.DHU
• EDNSOptionCode.ECS
• EDNSOptionCode.N3U
• EDNSOptionCode.DAU
• EDNSOptionCode.TCPKEEPALIVE
• EDNSOptionCode.COOKIE
• EDNSOptionCode.PADDING
• EDNSOptionCode.KEYTAG
• EDNSOptionCode.NSID
• EDNSOptionCode.CHAIN
• EDNSOptionCode.EXPIRE

Reference: https://www.iana.org/assignments/dns-parameters/dns-parameters.xhtml#dns-parameters-11

19.2.5 DNS Packet Sections

These constants represent the section in the DNS Packet.

• DNSSection.Question
• DNSSection.Answer
• DNSSection.Authority
• DNSSection.Additional

19.2.6 DNSAction

Changed in version 1.5.0: DNSAction.SpoofRaw has been added.
Changed in version 1.8.0: DNSAction.SpoofPacket has been added.

These constants represent an Action that can be returned from LuaAction() functions.

• DNSAction.Allow: let the query pass, skipping other rules
• DNSAction.Delay: delay the response for the specified milliseconds (UDP-only), continue to the next rule
• DNSAction.Drop: drop the query
• DNSAction.HeaderModify: indicate that the query has been turned into a response
• DNSAction.None: continue to the next rule
• DNSAction.NoOp: continue to the next rule (used for Dynamic Block actions where None has a different meaning)
• DNSAction.Nxdomain: return a response with a NXDomain rcode
• DNSAction.Pool: use the specified pool to forward this query
• DNSAction.Refused: return a response with a Refused rcode
• DNSAction.ServFail: return a response with a ServFail rcode
• DNSAction.Spoof: spoof the response using the supplied IPv4 (A), IPv6 (AAAA) or string (CNAME) value. TTL will be 60 seconds.
• DNSAction.SpoofPacket: spoof the response using the supplied raw packet
• DNSAction.SpoofRaw: spoof the response using the supplied raw value as record data (see also DNSQuestion:spoof() and dnsdist_ffi_dnsquestion_spoof_raw() to spoof multiple values)
• DNSAction.Truncate: truncate the response
• DNSAction.NoRecurse: set rd=0 on the query

19.2.7 DNSQType

Changed in version 1.4.0: The prefix is changed from dnsdist. to DNSQType.
Changed in version 1.7.0: The lookup fallback from dnsdist to DNSQType was removed.
All named QTypes are available as constants, prefixed with DNSQType, e.g.:
  • DNSQType.AAAA
  • DNSQType.AXFR
  • DNSQType.A
  • DNSQType.NS
  • DNSQType.SOA
  • etc.

19.2.8 DNSResponseAction

Changed in version 1.9.0: The DNSResponseAction.Truncate value was added.
These constants represent an Action that can be returned from LuaResponseAction() functions.
  • DNSResponseAction.Allow: let the response pass, skipping other rules
  • DNSResponseAction.Delay: delay the response for the specified milliseconds (UDP-only), continue to the next rule
  • DNSResponseAction.Drop: drop the response
  • DNSResponseAction.HeaderModify: indicate that the query has been turned into a response
  • DNSResponseAction.None: continue to the next rule
  • DNSResponseAction.ServFail: return a response with a ServFail rcode
  • DNSResponseAction.Truncate: truncate the response, removing all records from the answer, authority and additional sections if any

19.2. Constants
19.3 ComboAddress

IP addresses are moved around in a native format, called a **ComboAddress**. ComboAddresses can be IPv4 or IPv6, and unless you want to know, you don’t need to.

```plaintext
newCA(address) → ComboAddress
    Returns a ComboAddress based on address

Parameters address (string) – The IP address, with optional port, to represent.
```

class ComboAddress
A **ComboAddress** represents an IP address with possibly a port number. The object can be an IPv4 or an IPv6 address. It has these methods:

- **:getPort () → int**
  Returns the port number.

- **:ipdecrypt (key) → ComboAddress**
  Decrypt this IP address as described in https://powerdns.org/ipcipher

  Parameters key (string) – A 16 byte key. Note that this can be derived from a passphrase with the standalone function makeIPCipherKey

- **:ipencrypt (key) → ComboAddress**
  Encrypt this IP address as described in https://powerdns.org/ipcipher

  Parameters key (string) – A 16 byte key. Note that this can be derived from a passphrase with the standalone function makeIPCipherKey

- **:isIPv4 () → bool**
  Returns true if the address is an IPv4, false otherwise

- **:isIPv6 () → bool**
  Returns true if the address is an IPv6, false otherwise

- **:isMappedIPv4 () → bool**
  Returns true if the address is an IPv4 mapped into an IPv6, false otherwise

- **:mapToIPv4 () → ComboAddress**
  Convert an IPv4 address mapped in a v6 one into an IPv4. Returns a new ComboAddress

- **:toString () → string**
  Returns in human-friendly format

- **:toStringWithPort () → string**
  Returns in human-friendly format, with port number

- **:truncate (bits)**
  Truncate the ComboAddress to the specified number of bits. This essentially zeroes all bits after bits.

  Parameters bits (int) – Amount of bits to truncate to

19.4 Netmask

```plaintext
newNetmask(str) → Netmask
newNetmask(ca, bits) → Netmask
    New in version 1.5.0.

Returns a Netmask
```

Parameters
• **str** *(string)* – A netmask, like `192.0.2.0/24`.

• **ca** *(ComboAddress)* – A `ComboAddress`.

• **bits** *(int)* – The number of bits in this netmask.

### class Netmask

New in version 1.5.0: Represents a netmask.

: **getBits()** → **int**

Return the number of bits of this netmask, for example `24` for `192.0.2.0/24`.

: **getMaskedNetwork()** → **ComboAddress**

Return a `ComboAddress` object representing the base network of this netmask object after masking any additional bits if necessary (for example `192.0.2.0` if the netmask was constructed with `newNetmask('192.0.2.1/24')`).

: **empty()** → **bool**

Return true if the netmask is empty, meaning that the netmask has not been set to a proper value.

: **isIPv4()** → **bool**

Return true if the netmask is an IPv4 one.

: **isIPv6()** → **bool**

Return true if the netmask is an IPv6 one.

: **getNetwork()** → **ComboAddress**

Return a `ComboAddress` object representing the base network of this netmask object.

: **match(str)** → **bool**

Return true if the address passed in the `str` parameter belongs to this netmask.

**Parameters**

- **str** *(string)* – A network address, like `192.0.2.0`.

: **toString()** → **string**

Return a string representation of the netmask, for example `192.0.2.0/24`.

### 19.5 NetmaskGroup

newNMG() → NetmaskGroup

Returns a NetmaskGroup

### class NetmaskGroup

Represents a group of netmasks that can be used to match `ComboAddresses` against.

: **addMask(mask)**

: **addMasks(masks)**

Add one or more masks to the NMG.

**Parameters**

- **mask** *(string)* – Add this mask, prefix with `!` to exclude this mask from matching.

- **masks** *(table)* – Adds the keys of the table to the `NetmaskGroup`. It should be a table whose keys are `ComboAddress` objects and whose values are integers. The integer values of the table entries are ignored. The table is of the same type as the table returned by the `exceed*` functions.

: **addNMG(otherNMG)**

New in version 1.9.0.

Add all masks from an existing NMG to this NMG.

**Parameters**

- **otherNMG** *(NetmaskGroup)* – Add the masks from a `NetmaskGroup` to this one.
:match ([address]) → bool
Checks if address is matched by this NetmaskGroup.

Parameters address (ComboAddress) – The address to match.

:clear()
Clears the NetmaskGroup.

:size() → int
Returns number of netmasks in this NetmaskGroup.

19.6 DNSName objects

A DNSName object represents a name in the DNS. It has several functions that can manipulate it without conversions to strings. Creating a DNSName is done with the newDNSName():

```lua
myname = newDNSName("www.example.com")
```
dnsdist will complain loudly if the name is invalid (e.g. too long, dot in the wrong place).

The myname variable has several functions to get information from it

```lua
print(myname:countLabels()) -- prints "3"
print(myname:wirelength()) -- prints "17"
name2 = newDNSName("example.com")
if myname:isPartOf(name2) then -- prints "it is"
    print('it is')
end
```

19.6.1 Functions and methods of a DNSName

newDNSName (name) → DNSName
Returns the DNSName object of name.

Parameters name (string) – The name to create a DNSName for

class DNSName
A DNSName object represents a name in the DNS. It is returned by several functions and has several functions to programmatically interact with it.

:chopOff() → bool
Removes the left-most label and returns true. false is returned if no label was removed

:countLabels() → int
Returns the number of DNSLabels in the name

:isPartOf (name) → bool
Returns true if the DNSName is part of the DNS tree of name.

Parameters name (DNSName) – The name to check against

:makeRelative (name) → DNSName
New in version 1.8.0.

Provided that the current name is part of the supplied name, returns a new DNSName composed only of the labels that are below the supplied name (ie making www.powerdns.com relative to powerdns.com would return only www) Otherwise an empty (unset) DNSName is returned.

Parameters name (DNSName) – The name to make us relative against

:toDNSString() → string
Returns a wire format form of the DNSName, suitable for usage in SpoofRawAction().

:toString() → string
:toString() → string
    Returns a human-readable form of the DNSName.

:toStringNoDot() → string
    New in version 1.8.0.
    Returns a human-readable form of the DNSName, without the trailing dot.

:wirelength() → int
    Returns the length in bytes of the DNSName as it would be on the wire.

19.7 DNSNameSet objects

A DNSNameSet object is a set of DNSName objects. Based on std::unordered_set (hash table). Creating a DNSName is done with the newDNSNameSet():

```c
myset = newDNSNameSet()
```

The set can be filled by func:DNSNameSet:add:

```c
myset:add(newDNSName("domain1.tld"))
myset:add(newDNSName("domain2.tld"))
```

19.7.1 Functions and methods of a DNSNameSet

newDNSNameSet() → DNSNameSet
    Returns the DNSNameSet.

class DNSNameSet
    A DNSNameSet object is a set of DNSName objects.

    :add(name)
        Adds the name to the set.

    Parameters name (DNSName) – The name to add.

    :empty() → bool
        Returns true is the DNSNameSet is empty.

    :clear()
        Clean up the set.

    :toString() → string
        Returns a human-readable form of the DNSNameSet.

    :size() → int
        Returns the number of names in the set.

    :delete(name) → int
        Removes the name from the set. Returns the number of deleted elements.

        Parameters name (DNSName) – The name to remove.

    :check(name) → bool
        Returns true if the set contains the name.

        Parameters name (DNSName) – The name to check.
19.8 The DNSQuestion (dq) object

A DNSQuestion or dq object is available in several hooks and Lua actions. This object contains details about the current state of the question. This state can be modified from the various hooks.

class DNSQuestion
The DNSQuestion object has several attributes, many of them read-only:

   deviceID
       New in version 1.8.0.
       The identifier of the remote device, which will be exported via ProtoBuf if set.

   deviceName
       New in version 1.8.0.
       The name of the remote device, which will be exported via ProtoBuf if set.

   dh
       The DNSHeader (dh) object of this query.

   ecsOverride
       Whether an existing ECS value should be overridden, settable.

   ecsPrefixLength
       The ECS prefix length to use, settable.

   len
       The length of the data starting at DNSQuestion.dh, including any trailing bytes following the DNS message.

   localaddr
       ComboAddress of the local bind this question was received on.

   opcode

   pool
       New in version 1.8.0.
       The pool of servers to which this query will be routed.

   qclass
       QClass (as an unsigned integer) of this question. Can be compared against DNSClass.

   qname
       DNSName of this question.

   qtype
       QType (as an unsigned integer) of this question. Can be compared against the pre-defined constants like DNSQType.A, DNSQType.AAAA.

   remoteaddr
       ComboAddress of the remote client.

   requestorID
       New in version 1.8.0.
       The identifier of the requestor, which will be exported via ProtoBuf if set.

   rcode
       RCode (as an unsigned integer) of this question. Can be compared against RCode.

   size
       The total size of the buffer starting at DNSQuestion.dh.

   skipCache
       Whether to skip cache lookup / storing the answer for this question, settable.
tempFailureTTL
On a SERVFAIL or REFUSED from the backend, cache for this amount of seconds, settable.

tcp
Whether the query was received over TCP.

useECS
Whether to send ECS to the backend, settable.

It also supports the following methods:

: addProxyProtocolValue (type, value)  
New in version 1.6.0.
Add a proxy protocol TLV entry of type type and value to the current query.

Parameters
• type (int) – The type of the new value, ranging from 0 to 255 (both included)
• value (str) – The binary-safe value

:getContent () → str  
New in version 1.8.0.
Get the content of the DNS packet as a string

:getDO () → bool  
Get the value of the DNSSEC OK bit.

Returns true if the DO bit was set, false otherwise

:getEDNSOptions () → table  
Return the list of EDNS Options, if any.

Returns A table of EDNSOptionView objects, indexed on the ECS Option code

:getHTTPHeaders () → table  
New in version 1.4.0.
Changed in version 1.8.0: see keepIncomingHeaders on addDOHLocal()
Return the HTTP headers for a DoH query, as a table whose keys are the header names and values the header values. Since 1.8.0 it is necessary to set the keepIncomingHeaders option to true on addDOHLocal() to be able to use this method.

Returns A table of HTTP headers

:getHTTPHost () → string  
New in version 1.4.0.
Return the HTTP Host for a DoH query, which may or may not contain the port.

Returns The host of the DoH query

:getHTTPPath () → string  
New in version 1.4.0.
Return the HTTP path for a DoH query.

Returns The path part of the DoH query URI

:getHTTPQueryString () → string  
New in version 1.4.0.
Return the HTTP query string for a DoH query.

Returns The query string part of the DoH query URI

:getHTTPScheme () → string  
New in version 1.4.0.
Return the HTTP scheme for a DoH query.
**Returns** The scheme of the DoH query, for example http or https

: **getProtocol** () → string

New in version 1.7.0.

Return the transport protocol this query was received over, as a string. The possible values are:

- “Do53 UDP”
- “Do53 TCP”
- “DNSCrypt UDP”
- “DNSCrypt TCP”
- “DNS over TLS”
- “DNS over HTTPS”

**Returns** A string

: **getProxyProtocolValues** () → table

New in version 1.6.0.

Return a table of the Proxy Protocol values currently set for this query.

**Returns** A table whose keys are types and values are binary-safe strings

**DNSQuestion:** **getQueryTime** () → timespec

New in version 1.8.0.

Return the time at which the current query has been received, in whole seconds and nanoseconds since epoch, as a timespec object.

**Returns** A timespec object

: **getServerNameIndication** () → string

New in version 1.4.0.

Return the TLS Server Name Indication (SNI) value sent by the client over DoT or DoH, if any. See SNIRule() for more information, especially about the availability of SNI over DoH.

**Returns** A string containing the TLS SNI value, if any

: **getTag** (key) → string

Get the value of a tag stored into the DNSQuestion object.

**Parameters** key (string) – The tag’s key

**Returns** The tag’s value if it was set, an empty string otherwise

: **getTagArray** () → table

Get all the tags stored into the DNSQuestion object.

**Returns** A table of tags, using strings as keys and values

: **getTrailingData** () → string

New in version 1.4.0.

Get all data following the DNS message.

**Returns** The trailing data as a null-safe string

: **changeName** (newName) → bool

New in version 1.8.0.

Change the qname of the current query in the DNS payload. The reverse operation will have to be done on the response to set it back to the initial name, or the client will be confused and likely drop the response. See DNSResponse:changeName(). Returns false on failure, true on success.

**Parameters** newName (DNSName) – The new qname to use
**sendTrap** *(reason)*

Send an SNMP trap.

**Parameters**

- **reason** *(string)* – An optional string describing the reason why this trap was sent

**setContent** *(data)*

New in version 1.8.0.

Replace the whole DNS payload of the query with the supplied data. The new DNS payload must include the DNS header, whose ID will be adjusted to match the one of the existing query. For example, this replaces the whole DNS payload of queries for custom.async.tests.powerdns.com and type A, turning them into FORMERR responses, including EDNS with the DNSSECOK bit set and a UDP payload size of 1232:

```lua
function replaceQueryPayload(dq)
    local raw = ...
    dq:setContent(raw)
    return DNSAction.Allow
end
addAction(AndRule({QTypeRule(DNSQType.A), makeRule('custom.async.tests.powerdns.com')}), LuaAction(replaceQueryPayload))
```

**Parameters**

- **data** *(string)* – The raw DNS payload

**setEDNSOption** *(code, data)*

New in version 1.8.0.

Add arbitrary EDNS option and data to the query. Any existing EDNS content with the same option code will be overwritten.

**Parameters**

- **code** *(int)* – The EDNS option code
- **data** *(string)* – The EDNS option raw data

**setExtendedDNSError** *(infoCode, extraText)*

New in version 1.9.0: Set an Extended DNS Error status that will be added to the response corresponding to the current query.

**Parameters**

- **infoCode** *(int)* – The EDNS Extended DNS Error code
- **extraText** *(string)* – The optional EDNS Extended DNS Error extra text

**setHTTPResponse** *(status, body, contentType=“”)*

New in version 1.4.0.

Set the HTTP status code and content to immediately send back to the client. For HTTP redirects (3xx), the string supplied in body should be the URL to redirect to. For 200 responses, the value of the content type header can be specified via the contentType parameter. In order for the response to be sent, the QR bit should be set before returning and the function should return Action.HeaderModify.

**Parameters**

- **status** *(int)* – The HTTP status code to return
- **body** *(string)* – The body of the HTTP response, or a URL if the status code is a redirect (3xx)
- **contentType** *(string)* – The HTTP Content-Type header to return for a 200 response, ignored otherwise. Default is application/dns-message.
setNegativeAndAdditionalSOA\( (nxd, \text{zone}, \text{ttl}, \text{mname}, \text{rname}, \text{serial}, \text{refresh}, \text{retry}, \text{expire}, \text{minimum}) \)

New in version 1.5.0.

Turn a question into a response, either a NXDOMAIN or a NODATA one based on \( nxd \), setting the QR bit to 1 and adding a SOA record in the additional section.

**Parameters**

- \( nxd (bool) \) – Whether the answer is a NXDOMAIN (true) or a NODATA (false)
- \( \text{zone} (string) \) – The owner name for the SOA record
- \( \text{ttl} (int) \) – The TTL of the SOA record
- \( \text{mname} (string) \) – The mname of the SOA record
- \( \text{rname} (string) \) – The rname of the SOA record
- \( \text{serial} (int) \) – The value of the serial field in the SOA record
- \( \text{refresh} (int) \) – The value of the refresh field in the SOA record
- \( \text{retry} (int) \) – The value of the retry field in the SOA record
- \( \text{expire} (int) \) – The value of the expire field in the SOA record
- \( \text{minimum} (int) \) – The value of the minimum field in the SOA record

setProxyProtocolValues\( (values) \)

New in version 1.5.0.

Set the Proxy-Protocol Type-Length values to send to the backend along with this query.

**Parameters** values (table) – A table of types and values to send, for example: \{ [0x00] = "foo", [0x42] = "bar" \}. Note that the type must be an integer. Try to avoid these values: 0x01 - 0x05, 0x20 - 0x25, 0x30 as those are predefined in https://www.haproxy.org/download/2.3/doc/proxy-protocol.txt (search for PP2_TYPE_ALPN)

setRestartable()

New in version 1.8.0.

Make it possible to restart that query after receiving the response, for example to try a different pool of servers after receiving a SERVFAIL or a REFUSED response. Under the hood, this tells dnsdist to keep a copy of the initial query around so that we can send it a second time if needed. Copying the initial DNS payload has a small memory and CPU cost and thus is not done by default. See also DNSResponse::restart().

setTag\( (key, value) \)

Changed in version 1.7.0: Prior to 1.7.0 calling DNSQuestion::setTag() would not overwrite an existing tag value if already set.

Set a tag into the DNSQuestion object. Overwrites the value if any already exists.

**Parameters**

- \( key (string) \) – The tag’s key
- \( value (string) \) – The tag’s value

setTagArray\( (tags) \)

Changed in version 1.7.0: Prior to 1.7.0 calling DNSQuestion::setTagArray() would not overwrite existing tag values if already set.

Set an array of tags into the DNSQuestion object. Overwrites the values if any already exist.

**Parameters** tags (table) – A table of tags, using strings as keys and values
: **setTrailingData** *(tail) → bool*

New in version 1.4.0.

Set the data following the DNS message, overwriting anything already present.

**Parameters**
- **tail** *(string)* – The new data

**Returns**
true if the operation succeeded, false otherwise

: **spoof** *(iplips|rawraws [, typeForAny]*

New in version 1.6.0.

Changed in version 1.9.0: Optional parameter *typeForAny* added.

Forge a response with the specified record data as raw bytes. If you specify list of raws (it is assumed they match the query type), all will get spoofed in.

**Parameters**
- **ip** *(ComboAddress)* – The *ComboAddress* to be spoofed, e.g. `newCA("192.0.2.1")`.
- **ComboAddresses ips** *(table)* – The *ComboAddress'es* to be spoofed, e.g. `{ newCA("192.0.2.1"), newCA("192.0.2.2") }`.
- **raw** *(string)* – The raw string to be spoofed, e.g. `"\192\000\002\001"`.
- **raws** *(table)* – The raw strings to be spoofed, e.g. `{ "\192\000\002\001", "\192\000\002\002" }`.
- **typeForAny** *(int)* – The type to use for raw responses when the requested type is **ANY**, as using **ANY** for the type of the response record would not make sense.

: **suspend** *(asyncID, queryID, timeoutMS) → bool*

New in version 1.8.0.

Suspend the processing for the current query, making it asynchronous. The query is then placed into memory, in a map called the Asynchronous Holder, until it is either resumed or the supplied timeout kicks in. The object is stored under a key composed of the tuple *(asyncID, queryID)* which is needed to retrieve it later, which can be done via `getAsynchronousObject()`.

Note that the DNSQuestion object should NOT be accessed after successfully calling this method. Returns true on success and false on failure, indicating that the query has not been suspended and the normal processing will continue.

**Parameters**
- **asyncID** *(int)* – A numeric identifier used to identify the suspended query for later retrieval. Valid values range from 0 to 65535, both included.
- **queryID** *(int)* – A numeric identifier used to identify the suspended query for later retrieval. This ID does not have to match the query ID present in the initial DNS header. A given *(asyncID, queryID)* tuple should be unique at a given time. Valid values range from 0 to 65535, both included.
- **timeoutMS** *(int)* – The maximum duration this query will be kept in the asynchronous holder before being automatically resumed, in milliseconds.

### 19.9 DNSResponse object

**class DNSResponse**

This object has almost all the functions and members of a **DNSQuestion**, except for the following ones which are not available on a response:

- addProxyProtocolValue
- ecsOverride
If the value is really needed while the response is being processed, it is possible to set a tag while the query is processed, as tags will be passed to the response object. It also has additional methods:

**getSelectedBackend() → Server**

New in version 1.9.0.

Get the selected backend `Server` or nil

**editTTLs(func)**

The function `func` is invoked for every entry in the answer, authority and additional section.

`func` points to a function with the following prototype: `myFunc(section, qclass, qtype, ttl)`

All parameters to `func` are integers:

- `section` is the section in the packet and can be compared to `DNS Packet Sections`
- `qclass` is the QClass of the record. Can be compared to `DNSClass`
- `qtype` is the QType of the record. Can be e.g. compared to `DNSQType.A, DNSQType.AAAA` constants and the like.
- `ttl` is the current TTL

This function must return an integer with the new TTL. Setting this TTL to 0 leaves it unchanged

**Parameters**

`func(string)` – The function to call to edit TTLs.

**changeName(initialName) → bool**

New in version 1.8.0.

Change, in the DNS payload of the current response, the qname and the owner name of records to the supplied new name, if they are matching exactly the initial qname. This only makes if the reverse operation was performed on the query, or the client will be confused and likely drop the response. Note that only records whose owner name matches the qname in the initial response will be rewritten, and that only the owner name itself will be altered, not the content of the record rdata. For some records this might cause an issue with compression pointers contained in the payload, as they might no longer point to the correct position in the DNS payload. To prevent that, the records are checked against a list of supported record types, and the rewriting will not be performed if an unsupported type is present. As of 1.8.0 the list of supported types is: A, AAAA, DHCID, TXT, OPT, HINFO, DNSKEY, CDNSKEY, DS, CDS, DLV, SSHFP, KEY, CERT, TLSA, SMIMEA, OPENPGPKEY, NSEC, NSEC3, CSYNC, NSEC3PARAM, LOC, NID, L32, L64, EU48, EU64, URI, CAA, NS, PTR, CNAME,
DNAME, RRSIG, MX, SOA, SRV Therefore this functionality only makes sense when the initial query is requesting a very simple type, like A or AAAA.

See also DNSQuestion:changeName(). Returns false on failure, true on success.

Parameters initialName (DNSName) – The initial qname

:restart()

New in version 1.8.0.

Discard the received response and restart the processing of the query. For this function to be usable, the query should have been made restartable first, via DNSQuestion:setRestartable(). For example, to restart the processing after selecting a different pool of servers:

```lua
function makeQueryRestartable(dq)
    -- make it possible to restart that query later
    -- by keeping a copy of the initial DNS payload around
    dq:setRestartable()
    return DNSAction.None
end

function restartOnServFail(dr)
    -- if the query was SERVFAIL and not already tried on the restarted pool
    if dr.rcode == DNSRCode.SERVFAIL and dr.pool ~= 'restarted' then
        -- assign this query to a new pool
        dr.pool = 'restarted'
        -- discard the received response and
        -- restart the processing of the query
        dr:restart()
    end
    return DNSResponseAction.None
end

addAction(AllRule(), LuaAction(makeQueryRestartable))
addResponseAction(AllRule(), LuaResponseAction(restartOnServFail))
```

## 19.10 DNSHeader (dh) object

### class DNSHeader

This object holds a representation of a DNS packet’s header.

:getAA() conversion to bool

Get authoritative answer flag.

:getAD() conversion to bool

Get authentic data flag.

:getCD() conversion to bool

Get checking disabled flag.

:getID() conversion to int

New in version 1.8.0.

Get the ID.

:getRA() conversion to bool

Get recursion available flag.

:getRD() conversion to bool

Get recursion desired flag.

:getTC() conversion to bool

New in version 1.8.1.

Get the TC flag.
: **setAA** *(aa)*  
Set authoritative answer flag.

**Parameters aa** *(bool)* – State of the AA flag

: **setAD** *(ad)*  
Set authentic data flag.

**Parameters ad** *(bool)* – State of the AD flag

: **setCD** *(cd)*  
Set checking disabled flag.

**Parameters cd** *(bool)* – State of the CD flag

: **setQR** *(qr)*  
Set Query/Response flag. Setting QR to true means “This is an answer packet”.

**Parameters qr** *(bool)* – State of the QR flag

: **setRA** *(ra)*  
Set recursion available flag.

**Parameters ra** *(bool)* – State of the RA flag

: **setRD** *(rd)*  
Set recursion desired flag.

**Parameters rd** *(bool)* – State of the RD flag

: **setTC** *(tc)*  
Set truncation flag (TC).

**Parameters tc** *(bool)* – State of the TC flag

### 19.11 EDNSOptionView object

class EDNSOptionView
An object that represents the values of a single EDNS option received in a query.

: **count** ()
The number of values for this EDNS option.

: **getValues** ()
Return a table of NULL-safe strings values for this EDNS option.

### 19.12 AsynchronousObject object

class AsynchronousObject
New in version 1.8.0.
This object holds a representation of a DNS query or response that has been suspended.

: **drop** () → bool
Drop that object immediately, without resuming it. Returns true on success, false on failure.

: **getDQ** () → DNSQuestion
Return a DNSQuestion object for the suspended object.

: **getDR** () → DNSResponse
Return a DNSResponse object for the suspended object.
**resume()** → bool
Resume the processing of the suspended object. For a question, it means first checking whether it was turned into a response, and sending the response out if it was. Otherwise do a cache-lookup: on a cache-hit, the response will be sent immediately. On a cache-miss, it means dnsdist will select a backend and send the query to the backend. For a response, it means inserting into the cache if needed and sending the response to the backend. Note that the AsynchronousObject object should NOT be accessed after successfully calling this method. Returns true on success, false on failure.

**setRCode(rCode, clearRecords)** → bool
Set the response code in the DNS header of the current object to the supplied value, optionally removing all records from the existing payload, if any. Returns true on success, false on failure.

Parameters

- **code (int)** – The response code to set
- **clearRecords (bool)** – Whether to clear all records from the existing payload, if any

**getAsynchronousObject(asyncID, queryID)** → AsynchronousObject
New in version 1.8.0.
Retrieves an asynchronous object stored into the Asynchronous holder.

Parameter:

- **asyncID** – A numeric identifier used to identify the query when it was suspended
- **queryID** – A numeric identifier used to identify the query when it was suspended

## 19.13 eBPF functions and objects

These are all the functions, objects and methods related to the eBPF Socket Filtering.

**addBPFFilterDynBlocks(addresses, dynbpf[, seconds=10], msg)**
This is the eBPF equivalent of `addDynBlocks()`, blocking a set of addresses for (optionally) a number of seconds, using an eBPF dynamic filter. The default number of seconds to block for is 10. Since 1.6.0, the use of a `DynBlockRulesGroup` is a much more efficient way of doing the same thing.

Parameters

- **addresses** – set of Addresses as returned by an `exceed` function
- **dynbpf (DynBPFFilter)** – The dynamic eBPF filter to use
- **seconds (int)** – The number of seconds this block to expire
- **msg (str)** – A message to display while inserting the block

**newBPFFilter(options)** → BPFFilter
**newBPFFilter(v4Parameters, v6Parameters, qnamesParameters) → BPFFilter (1.7.x)**
**newBPFFilter(maxV4, maxV6, maxQNames) → BPFFilter (before 1.7.0)**

Changed in version 1.7.0: This function now supports a table for each parameters, and the ability to use pinned eBPF maps.

Changed in version 1.8.0: This function now gets its parameters via a table.

Return a new eBPF socket filter with a maximum of `maxV4` IPv4, `maxV6` IPv6 and `maxQNames` qname entries in the block tables. Maps can be pinned to a filesystem path, which makes their content persistent across restarts and allows external programs to read their content and to add new entries. dnsdist will try to load maps that are pinned to a filesystem path on startups, inheriting any existing entries, and fall back to creating them if they do not exist yet. Note that the user dnsdist is running under must have the right privileges to read and write to the given file, and to go through all the directories in the path leading to that file. The pinned path must be on a filesystem of type BPF, usually below `/sys/fs/bpf/`.

## 19.13. eBPF functions and objects
**Parameters options** \((table)\) – A table with key: value pairs with options.

Options:

- **ipv4MaxItems**: int - The maximum number of entries in the IPv4 map. Default is 0 which will not allow any entry at all.
- **ipv4PinnedPath**: str - The filesystem path this map should be pinned to.
- **ipv6MaxItems**: int - The maximum number of entries in the IPv6 map. Default is 0 which will not allow any entry at all.
- **ipv6PinnedPath**: str - The filesystem path this map should be pinned to.
- **cidr4MaxItems**: int - The maximum number of entries in the IPv4 range block map. Default is 0 which will not allow any entry at all.
- **cidr4PinnedPath**: str - The filesystem path this map should be pinned to.
- **cidr6MaxItems**: int - The maximum number of entries in the IPv6 range block map. Default is 0 which will not allow any entry at all.
- **cidr6PinnedPath**: str - The filesystem path this map should be pinned to.
- **qnamesMaxItems**: int - The maximum number of entries in the qname map. Default is 0 which will not allow any entry at all.
- **qnamesPinnedPath**: str - The filesystem path this map should be pinned to.
- **external**: bool - If set to true, DNSDist does not load the internal eBPF program.

```python
newDynBPFFilter (bpf) → DynBPFFilter
```

Return a new dynamic eBPF filter associated to a given BPF Filter.

**Parameters**

- **bpf**: BPFFilter – The underlying eBPF filter

```python
setDefaultBPFFilter (filter)
```

When used at configuration time, the corresponding BPFFilter will be attached to every bind.

**Parameters**

- **filter**: BPFFilter – The filter to attach

```python
registerDynBPFFilter (dynbpf)
```

Register a DynBPFFilter filter so that it appears in the web interface and the API.

**Parameters**

- **dynbpf**: DynBPFFilter – The dynamic eBPF filter to register

```python
unregisterDynBPFFilter (dynbpf)
```

Remove a DynBPFFilter filter from the web interface and the API.

**Parameters**

- **dynbpf**: DynBPFFilter – The dynamic eBPF filter to unregister

```python
class BPFFilter
```

Represents an eBPF filter

```python
:attachToAllBinds()
```

Attach this filter to every bind already defined. This is the run-time equivalent of `setDefaultBPFFilter()`. This method can be used at run-time only.

```python
:block(address)
```

Block this address

**Parameters**

- **address**: ComboAddress – The address to block

```python
:addRangeRule (Netmask, action[, force=false])
```

New in version 1.8.0.

Block all IP addresses in this range.
DNSDist eBPF code first checks if an exact IP match is found, then if a range matches, and finally if a DNSName does.

**Parameters**

- **Netmask (string)** – The ip range to block, allow or truncate
- **action (int)** – set action to 0 to allow a range, set action to 1 to block a range, set action to 2 to truncate a range.
- **force (bool)** – When force is set to true, DNSDist always accepts adding a new item to BPF maps, even if the item to be added may already be included in the larger network range.

```
:blockQName (name[, qtype=255])
```

Block queries for this exact qname. An optional qtype can be used, defaults to 255.

**Parameters**

- **name (DNSName)** – The name to block
- **qtype (int)** – QType to block

```
:getStats ()
```

Print the block tables.

```
:unblock (address)
```

Unblock this address.

**Parameters**

- **address (ComboAddress)** – The address to unblock

```
:rmRangeRule (Netmask)
```

New in version 1.8.0.

**Parameters**

- **string (Netmask)** – The rule you want to remove

```
:lsRangeRule ()
```

New in version 1.8.0.

List all range rule.

```
:unblockQName (name[, qtype=255])
```

Remove this qname from the block list.

**Parameters**

- **name (DNSName)** – the name to unblock
- **qtype (int)** – The qtype to unblock

### class DynBPFFilter

Represents a dynamic eBPF filter, allowing the use of ephemeral rules to an existing eBPF filter. Note that since 1.6.0 the default BPF filter set via `setDefaultBPFFilter()` will automatically be used by a `DynBlockRulesGroup`, becoming the preferred way of dealing with ephemeral rules.

```
:purgeExpired ()
```

Remove the expired ephemeral rules associated with this filter.

```
:excludeRange (netmasks)
```

Exclude this range, or list of ranges, meaning that no dynamic block will ever be inserted for clients in that range. Default to empty, meaning rules are applied to all ranges. When used in combination with `DynBPFFilter:includeRange()`, the more specific entry wins.

**Parameters**

- **or list of str netmasks (str)** – A netmask, or list of netmasks, as strings, like for example “192.0.2.1/24”

```
:includeRange (netmasks)
```

Include this range, or list of ranges, meaning that rules will be applied to this range. When used in combination with `DynBPFFilter:excludeRange()`, the more specific entry wins.
Parameters or list of str netmasks (str) – A netmask, or list of netmasks, as strings, like for example “192.0.2.1/24”

19.14 DNSCrypt objects and functions

addDNSCryptBind (address, provider, certFile(s), keyFile(s)[, options])

Changed in version 1.4.0: Removed doTCP from the options. A listen socket on TCP is always created. certFile(s) and keyFile(s) now accept a list of files.

Changed in version 1.5.0: Added tcpListenQueueSize parameter.

Changed in version 1.6.0: Added maxInFlight and maxConcurrentTCPConnections parameters.

Adds a DNSCrypt listen socket on address.

Parameters

• address (string) – The address and port to listen on
• provider (string) – The provider name for this bind
• certFile(s) (str) – The path to a X.509 certificate file in PEM format, or a list of paths to such files.
• keyFile(s) (str) – The path to the private key file corresponding to the certificate, or a list of paths to such files, whose order should match the certFile(s) ones.
• options (table) – A table with key: value pairs with options (see below)

Options:

• doTCP=true: bool - Also bind on TCP on address, removed in 1.4.0.
• reusePort=false: bool - Set the SO_REUSEPORT socket option.
• tcpFastOpenQueueSize=0: int - Set the TCP Fast Open queue size, enabling TCP Fast Open when available and the value is larger than 0
• interface": str - Sets the network interface to use
• cpus={}: table - Set the CPU affinity for this listener thread, asking the scheduler to run it on a single CPU id, or a set of CPU ids. This parameter is only available if the OS provides the pthread_setaffinity_np() function.
• tcpListenQueueSize=SOMAXCONN: int - Set the size of the listen queue. Default is SOMAXCONN.
• maxInFlight=0: int - Maximum number of in-flight queries. The default is 0, which disables out-of-order processing.
• maxConcurrentTCPConnections=0: int - Maximum number of concurrent incoming TCP connections. The default is 0 which means unlimited.

generateDNSCryptProviderKeys (publicKey, privateKey)

Generate a new provider keypair and write them to publicKey and privateKey.

Parameters

• publicKey (string) – path to write the public key to
• privateKey (string) – path to write the private key to

generateDNSCryptCertificate (privatekey, certificate, keyfile, serial, validFrom, validUntil[, version])

generate a new resolver private key and related certificate, valid from the validFrom UNIX timestamp until the validUntil one, signed with the provider private key.

Parameters
• `privatekey (string)` – Path to the private key of the provider
• `certificate (string)` – Path where to write the certificate file
• `keyfile (string)` – Path where to write the private key for the certificate
• `serial (int)` – The certificate’s serial number
• `validFrom (int)` – Unix timestamp from when the certificate will be valid
• `validUntil (int)` – Unix timestamp until when the certificate will be valid
• `version (DNSCryptExchangeVersion)` – The exchange version to use. Possible values are `DNSCryptExchangeVersion::VERSION1` (default, X25519-XSalsa20-Poly1305) and `DNSCryptExchangeVersion::VERSION2` (X25519-XChacha20-Poly1305)

`printDNSCryptProviderFingerprint(keyfile)`
Display the fingerprint of the provided resolver public key

Parameters `keyfile (string)` – Path to the key file

`showDNSCryptBinds()`
Display the currently configured DNSCrypt binds

`getDNSCryptBind(n) → DNSCryptContext`
Return the `DNSCryptContext` object corresponding to the bind n.

`getDNSCryptBindCount()`
New in version 1.5.0.
Return the number of DNSCrypt binds.

19.14.1 Certificates

class DNSCryptCert
Represents a DNSCrypt certificate.

`:getClientMagic() → string`
Return this certificate’s client magic value.

`:getEsVersion() → string`
Return the cryptographic construction to use with this certificate.

`:getMagic() → string`
Return the certificate magic number.

`:getProtocolMinorVersion() → string`
Return this certificate’s minor version.

`:getResolverPublicKey() → string`
Return the public key corresponding to this certificate.

`:getSerial() → int`
Return the certificate serial number.

`:getSignature() → string`
Return this certificate’s signature.

`:getTSEnd() → int`
Return the date the certificate is valid from, as a Unix timestamp.

`:getTSStart() → int`
Return the date the certificate is valid until (inclusive), as a Unix timestamp.

class DNSCryptCertificatePair
Represents a pair of DNSCrypt certificate and associated key.

:getCertificate () → DNSCryptCert
Return the certificate.

:isActive () → bool
Return whether this pair is active and will be advertised to clients.

19.14.3 Context

class DNSCryptContext
Represents a DNSCrypt content. Can be used to rotate certs.

:addNewCertificate (cert, key[.active])
Add a new certificate to the given context. Active certificates are advertised to clients, inactive ones are not.

Parameters

• cert (DNSCryptCert) – The certificate to add to the context
• key (DNSCryptPrivateKey) – The private key corresponding to the certificate
• active (bool) – Whether the certificate should be advertised to clients. Default is true

:generateAndLoadInMemoryCertificate (keyfile, serial, begin, end[.version])
Generate a new resolver key and the associated certificate in-memory, sign it with the provided provider key, and add it to the context

Parameters

• keyfile (string) – Path to the provider key file to use
• serial (int) – The serial number of the certificate
• begin (int) – Unix timestamp from when the certificate is valid
• end (int) – Unix timestamp from until the certificate is valid
• version (DNSCryptExchangeVersion) – The exchange version to use. Possible values are DNSCryptExchangeVersion::VERSION1 (default, X25519-XSalsa20Poly1305) and DNSCryptExchangeVersion::VERSION2 (X25519-XChacha20Poly1305)

:getCertificate (index) → DNSCryptCert
Return the certificate with index index.

Parameters index (int) – The index of the certificate, starting at 0

:getCertificatePair (index) → DNSCryptCertificatePair
Return the certificate pair with index index.

Parameters index (int) – The index of the certificate, starting at 0

:getCertificatePair (index) → table of DNSCryptCertificatePair
Return a table of certificate pairs.

:getProviderName () → string
Return the provider name

:loadNewCertificate (certificate, keyfile[.active])
Load a new certificate and the corresponding private key. If active is false, the certificate will not be advertised to clients but can still be used to answer queries tied to it.
Parameters

- certificate\textit{(string)} – Path to a certificate file
- keyfile\textit{(string)} – Path to the corresponding key file
- active\textit{(bool)} – Whether the certificate should be marked as active. Default is true

:markActive\textit{(serial)}
Mark the certificate with serial \textit{serial} as active, meaning it will be advertised to clients.

Parameters \textit{serial}(int) – The serial of the number to mark as active

:markInactive\textit{(serial)}
Mark the certificate with serial \textit{serial} as inactive, meaning it will not be advertised to clients but can still be used to answer queries tied to this certificate.

Parameters \textit{serial}(int) – The serial of the number to mark as inactive

:printCertificates()
Print all the certificates.

:reloadCertificates()
New in version 1.6.0.
Reload the current TLS certificate and key pairs.

:removeInactiveCertificate\textit{(serial)}
Remove the certificate with serial \textit{serial}. It will not be possible to answer queries tied to this certificate, so it should have been marked as inactive for a certain time before that. Active certificates should be marked as inactive before they can be removed.

Parameters \textit{serial}(int) – The serial of the number to remove

19.15 DNS Parser

Since 1.8.0, dnsdist contains a limited DNS parser class that can be used to inspect the content of DNS queries and responses in Lua.

The first step is to get the content of the DNS payload into a Lua string, for example using \texttt{DNSQuestion:getContent()}, or \texttt{DNSResponse:getContent()}, and then to create a \texttt{DNSPacketOverlay} object:

```lua
function dumpPacket(dq)
    local packet = dq:getContent()
    local overlay = newDNSPacketOverlay(packet)
    print(overlay.qname)
    print(overlay.qtype)
    print(overlay.qclass)
    local count = overlay:getRecordsCountInSection(DNSSection.Answer)
    print(count)
    for idx=0, count-1 do
        local record = overlay:getRecord(idx)
        print(record.name)
        print(record.type)
        print(record.class)
        print(record.ttl)
        print(record.place)
        print(record.contentLength)
        print(record.contentOffset)
    end
    return DNSAction.None
end
addAction(AllRule(), LuaAction(dumpPacket))
```

19.15. DNS Parser
newDNSPacketOverlay (packet) → DNSPacketOverlay

New in version 1.8.0.

Returns a DNSPacketOverlay

Parameters packet (str) – The DNS payload

19.15.1 DNSPacketOverlay

class DNSPacketOverlay

New in version 1.8.0.

The DNSPacketOverlay object has several attributes, all of them read-only:

qname

The qname of this packet, as a DNSName objects.

qtype

The type of the query in this packet.

qclass

The class of the query in this packet.

dh

It also supports the following methods:

:getRecordsCountInSection (section) → int

Returns the number of records in the ANSWER (1), AUTHORITY (2) and ADDITIONAL (3) DNS Packet Sections of this packet. The number of records in the QUESTION (0) is always set to 0, look at the dnsheader if you need the actual qdcount.

Parameters section (int) – The section, see above

:getRecord (idx) → DNSRecord

Get the record at the requested position. The records in the QUESTION sections are not taken into account, so the first record in the answer section would be at position 0.

Parameters idx (int) – The position of the requested record

19.16 DNSRecord object

class DNSRecord

New in version 1.8.0.

This object represents an unparsed DNS record, as returned by the DNSPacketOverlay class. It has several attributes, all of them read-only:

name

The name of this record, as a DNSName objects.

type

The type of this record.

class

The class of this record.

ttl

The TTL of this record.

place

The place (section) of this record.

contentLength

The length, in bytes, of the rdata content of this record.
contentOffset
The offset since the beginning of the DNS payload, in bytes, at which the rdata content of this record starts.

19.17 Protobuf Logging Reference

newRemoteLogger \(\text{[address}, \text{timeout}=2, \text{maxQueuedEntries}=100, \text{reconnectWaitTime}=1]\)
Create a Remote Logger object, to use with RemoteLogAction() and RemoteLogResponseAction().

Parameters
- \text{address} (string) – An IP:PORT combination where the logger is listening
- \text{timeout} (int) – TCP connect timeout in seconds
- \text{maxQueuedEntries} (int) – Queue this many messages before dropping new ones (e.g. when the remote listener closes the connection)
- \text{reconnectWaitTime} (int) – Time in seconds between reconnection attempts

class DNSDistProtoBufMessage
This object represents a single protobuf message as emitted by dnsdist.

: addResponseRR (name, type, class, ttl, blob)
Add a response RR to the protobuf message.

Parameters
- \text{name} (string) – The RR name.
- \text{type} (int) – The RR type.
- \text{class} (int) – The RR class.
- \text{ttl} (int) – The RR TTL.
- \text{blob} (string) – The RR binary content.

: setBytes (bytes)
Set the size of the query

Parameters \text{bytes} (int) – Number of bytes in the query.

: setEDNSSubnet (netmask)
Set the EDNS Subnet to \text{netmask}.

Parameters \text{netmask} (string) – The netmask to set to.

: setQueryTime (sec, usec)
In a response message, set the time at which the query has been received.

Parameters
- \text{sec} (int) – Unix timestamp when the query was received.
- \text{usec} (int) – The microsecond the query was received.

: setQuestion (name, qtype, qclass)
Set the question in the protobuf message.

Parameters
- \text{name} (DNSName) – The qname of the question
- \text{qtype} (int) – The qtype of the question
- \text{qclass} (int) – The qclass of the question
: `setProtobufResponseType (sec, usec)`
Change the protobuf response type from a query to a response, and optionally set the query time.

Parameters
- `sec (int)` – Optional query time in seconds.
- `usec (int)` – Optional query time in additional micro-seconds.

: `setRequestor (address[, port])`
Changed in version 1.5.0: `port` optional parameter added.
Set the requestor’s address.

Parameters
- `address (ComboAddress)` – The address to set to
- `port (int)` – The requestor source port

: `setRequestorFromString (address[, port])`
Changed in version 1.5.0: `port` optional parameter added.
Set the requestor’s address from a string.

Parameters
- `address (string)` – The address to set to
- `port (int)` – The requestor source port

: `setResponder (address[, port])`
Changed in version 1.5.0: `port` optional parameter added.
Set the responder’s address.

Parameters
- `address (ComboAddress)` – The address to set to
- `port (int)` – The responder port

: `setResponderFromString (address[, port])`
Changed in version 1.5.0: `port` optional parameter added.
Set the responder’s address.

Parameters
- `address (string)` – The address to set to
- `port (int)` – The responder port

: `setResponseCode (rcode)`
Set the response code of the query.

Parameters
- `rcode (int)` – The response code of the answer

: `setServerIdentity (id)`
Set the server identify field.

Parameters
- `id (string)` – The server ID

: `setTag (value)`
Add a tag to the list of tags.

Parameters
- `value (string)` – The tag value

: `setTagArray (valueList)`
Add a list of tags.

Parameters
- `tags (table)` – A list of tags as strings
`:setTime (sec, usec)`
Set the time at which the query or response has been received.

**Parameters**

- `sec (int)` – Unix timestamp when the query was received.
- `usec (int)` – The microsecond the query was received.

`:toDebugString () → string`
Return a string containing the content of the message

## 19.18 dnstap Logging Reference

dnstap is a flexible, structured binary log format for DNS software. Reader implementations in various languages exist.

dnsdist supports dnstap since version 1.3.0.

Canonically, dnstap is sent over a FrameStream socket, either a local AF_UNIX (see `newFrameStreamUnixLogger()` or a TCP/IP socket (see `newFrameStreamTcpLogger()`). As an extension, dnsdist can send raw dnstap protobuf messages over a `newRemoteLogger()`.

To use FrameStream transport, dnsdist must have been built with `libfstrm`.

`newFrameStreamUnixLogger (path[, options])`
Changed in version 1.5.0: Added the optional parameter `options`.

Create a Frame Stream Logger object, to use with `DnstapLogAction()` and `DnstapLogResponseAction()`. This version will log to a local AF_UNIX socket.

**Parameters**

- `path (string)` – A local AF_UNIX socket path. Note that most platforms have a rather short limit on the length.
- `options (table)` – A table with key: value pairs with options.

The following options apply to the settings of the framestream library. Refer to the documentation of that library for the default and allowed values for these options, as well as their exact descriptions. For all these options, absence or a zero value has the effect of using the library-provided default value.

- `bufferHint=0`: unsigned
- `flushTimeout=0`: unsigned
- `inputQueueSize=0`: unsigned
- `outputQueueSize=0`: unsigned
- `queueNotifyThreshold=0`: unsigned
- `reopenInterval=0`: unsigned

`newFrameStreamTcpLogger (address[, options])`
Changed in version 1.5.0: Added the optional parameter `options`.

Create a Frame Stream Logger object, to use with `DnstapLogAction()` and `DnstapLogResponseAction()`. This version will log to a possibly remote TCP socket. Needs `tcp_writer` support in `libfstrm`.

**Parameters**

- `address (string)` – An IP:PORT combination where the logger will connect to.
- `options (table)` – A table with key: value pairs with options.
The following options apply to the settings of the framestream library. Refer to the documentation of that library for the default and allowed values for these options, as well as their exact descriptions. For all these options, absence or a zero value has the effect of using the library-provided default value.

- `bufferHint=0: unsigned`
- `flushTimeout=0: unsigned`
- `inputQueueSize=0: unsigned`
- `outputQueueSize=0: unsigned`
- `queueNotifyThreshold=0: unsigned`
- `reopenInterval=0: unsigned`

**class DnstapMessage**

This object represents a single dnstap message as emitted by `dnsdist`.

**classmethod DnstapMessage:setExtra(extraData)**

Sets the dnstap "extra" field.

**Parameters**
extraData (string) – Extra data stuffed into the dnstap "extra" field.

**classmethod DnstapMessage:toDebugString()** → string

Return a string containing the content of the message

### 19.19 Carbon export

**carbonServer(serverIP[, ourname[, interval[, namespace[, instance]]]])**

Export statistics to a Carbon / Graphite / Metronome server.

**Parameters**

- `serverIP (string)` – Indicates the IP address where the statistics should be sent
- `ourname (string)` – An optional string specifying the hostname that should be used
- `interval (int)` – An optional unsigned integer indicating the interval in seconds between exports
- `namespace (string)` – An optional string specifying the namespace name that should be used
- `instance (string)` – An optional string specifying the instance name that should be used

### 19.20 SNMP reporting

**snmpAgent(enableTraps[, daemonSocket])**

Enable SNMP support.

**Parameters**

- `enableTraps (bool)` – Indicates whether traps should be sent
- `daemonSocket (string)` – A string specifying how to connect to the daemon agent. This is a file path to a unix socket, but e.g. tcp:localhost:705 can be used as well. By default, SNMP agent’s default socket is used.

**sendCustomTrap(message)**

Send a custom SNMP trap from Lua.

**Parameters**
message (string) – The message to include in the sent trap
19.21 Tuning related functions

**setDoHDNSupstreamCleanupInterval** *(interval)*

New in version 1.7.0.

Set how often, in seconds, the outgoing DoH connections to backends of a given worker thread are scanned to expunge the ones that are no longer usable. The default is 60 so once per minute and per worker thread.

**Parameters**

interval *(int)* – The interval in seconds.

**setDoHDNSupstreamMaxIdleTime** *(max)*

New in version 1.7.0.

Set how long, in seconds, an outgoing DoH connection to a backend might stay idle before being closed. The default is 300 so 5 minutes.

**Parameters**

max *(int)* – The maximum time in seconds.

**setMaxIdleDoHConnectionsPerDownstream** *(max)*

New in version 1.7.0.

Set the maximum number of inactive DoH connections to a backend cached by each DoH worker thread. These connections can be reused when a new query comes in, instead of having to establish a new connection. dnsdist regularly checks whether the other end has closed any cached connection, closing them in that case.

**Parameters**

max *(int)* – The maximum number of inactive connections to keep. Default is 10, so 10 connections per backend and per DoH worker thread.

**setMaxCachedTCPConnectionsPerDownstream** *(max)*

New in version 1.6.0.

Set the maximum number of inactive TCP connections to a backend cached by each TCP worker thread. These connections can be reused when a new query comes in, instead of having to establish a new connection. dnsdist regularly checks whether the other end has closed any cached connection, closing them in that case.

**Parameters**

max *(int)* – The maximum number of inactive connections to keep. Default is 10, so 10 connections per backend and per TCP worker thread.

**setMaxTCPClientThreads** *(num)*

Changed in version 1.6.0: Before 1.6.0 the default value was 10.

Changed in version 1.7.0: The default value has been set back to 10.

Set the maximum of TCP client threads, handling TCP connections. Before 1.4.0 a TCP thread could only handle a single incoming TCP connection at a time, while after 1.4.0 it can handle a larger number of them simultaneously.

Note that before 1.6.0 the TCP worker threads were created at runtime, adding a new thread when the existing ones seemed to struggle with the load, until the maximum number of threads had been reached. Starting with 1.6.0 the configured number of worker threads are immediately created at startup.

In 1.6.0 the default value was at least 10 TCP workers, but could be more if there is more than 10 TCP listeners (added via addDNSCryptBind(), addLocal(), or addTLSLocal()). In that last case there would have been as many TCP workers as TCP listeners. This led to issues in setups with a large number of TCP listeners and was therefore reverted back to 10 in 1.7.0.

**Parameters**

num *(int)* – The number of TCP worker threads.

**setMaxTCPConnectionDuration** *(num)*

Set the maximum duration of an incoming TCP connection, in seconds. 0 (the default) means unlimited.

**Parameters**

num *(int)* –

**setMaxTCPConnectionsPerClient** *(num)*

Set the maximum number of TCP connections per client. 0 (the default) means unlimited.
**Parameters** `num (int)` –

`setMaxTCPQueriesPerConnection (num)`
Set the maximum number of queries in an incoming TCP connection. 0 (the default) means unlimited

**Parameters** `num (int)` –

`setMaxTCPQueueConnections (num)`
Changed in version 1.6.0: Before 1.6.0 the default value was 1000 on all systems.
Set the maximum number of TCP connections queued (waiting to be picked up by a client thread), defaults to 1000 (10000 on Linux since 1.6.0). 0 means unlimited

**Parameters** `num (int)` –

`setMaxUDPQueryOutstanding (num)`
Changed in version 1.4.0: Before 1.4.0 the default value was 10240
Set the maximum number of outstanding UDP queries to a given backend server. This can only be set at configuration time and defaults to 65535 (10240 before 1.4.0)

**Parameters** `num (int)` –

`setCacheCleaningDelay (num)`
Set the interval in seconds between two runs of the cache cleaning algorithm, removing expired entries. Default is every 60s

**Parameters** `num (int)` –

`setCacheCleaningPercentage (num)`
Set the percentage of the cache that the cache cleaning algorithm will try to free by removing expired entries. By default (100), all expired entries are removed

**Parameters** `num (int)` –

`setOutgoingDoHWorkerThreads (num)`
New in version 1.7.0.
Set the number of worker threads to use for outgoing DoH. That number defaults to 0 but is automatically raised to 1 when DoH is enabled on at least one backend.

`setStaleCacheEntriesTTL (num)`
Allows using cache entries expired for at most n seconds when no backend available to answer for a query

**Parameters** `num (int)` –

`setTCPDownstreamCleanupInterval (interval)`
New in version 1.6.0.
Set how often, in seconds, the outgoing TCP connections to backends of a given worker thread are scanned to expunge the ones that are no longer usable. The default is 60 so once per minute and per worker thread.

**Parameters** `interval (int)` – The interval in seconds.

`setDoHDownstreamMaxIdleTime (max)`
New in version 1.7.0.
Set how long, in seconds, an outgoing DoH connection to a backend might stay idle before being closed. The default is 300 so 5 minutes.

**Parameters** `max (int)` – The maximum time in seconds.

`setRandomizedIdsOverUDP (val)`
New in version 1.8.0.
Setting this parameter to true (default is false) will randomize the IDs in outgoing UDP queries, at a small performance cost, ignoring the `setMaxUDPQueryOutstanding()` value. This is only useful if the path between dnsdist and the backend is not trusted and the ‘TCP-only’, DNS over TLS or DNS over HTTPS transports cannot be used. See also `setRandomizedOutgoingSockets()`. The default is to use a linearly increasing counter from 0 to 65535, wrapping back to 0 when necessary.
**setRandomizedOutgoingSockets** *(val)*

New in version 1.8.0.

Setting this parameter to true (default is false) will randomize the outgoing socket used when forwarding a query to a backend. The default is to use a round-robin mechanism to select the outgoing socket. This requires configuring the backend to use more than one outgoing socket via the `sockets` parameter of `newServer()` to be of any use, and only makes sense if the path between dnsdist and the backend is not trusted and the ‘TCP-only’, DNS over TLS or DNS over HTTPS transports cannot be used. See also `setRandomizedIdsOverUDP()`.

**setTCPInternalPipeBufferSize** *(size)*

New in version 1.6.0.

Set the size in bytes of the internal buffer of the pipes used internally to distribute connections to TCP (and DoT) workers threads. Requires support for `F_SETPIPE_SZ` which is present in Linux since 2.6.35. The actual size might be rounded up to a multiple of a page size. 0 means that the OS default size is used. The default value is 0, except on Linux where it is 1048576 since 1.6.0.

**Parameters**

- **size** *(int)* – The size in bytes.

**setTCPUseSinglePipe** *(val)*

Deprecated since version 1.6.0.

Whether the incoming TCP connections should be put into a single queue instead of using per-thread queues. Defaults to false. That option was useful before 1.4.0 when a single TCP connection could block a TCP worker thread, but should not be used in recent versions where the per-thread queues model avoids waking up all idle workers when a new connection arrives. This option will be removed in 1.7.0.

**Parameters**

- **val** *(bool)* –

**setTCPRecvTimeout** *(num)*

Set the read timeout on TCP connections from the client, in seconds. Defaults to 2

**Parameters**

- **num** *(int)* –

**setTCPSendTimeout** *(num)*

Set the write timeout on TCP connections from the client, in seconds. Defaults to 2

**Parameters**

- **num** *(int)* –

**setUDPMultipleMessagesVectorSize** *(num)*

Set the maximum number of UDP queries messages to accept in a single `recvmmsg()` call. Only available if the underlying OS support `recvmmsg()` with the MSG_WAITFORONE option. Defaults to 1, which means only query at a time is accepted, using `recvmsg()` instead of `recvmmsg()`.

**Parameters**

- **num** *(int)* – maximum number of UDP queries to accept

**setUDPSocketBufferSizes** *(recv, send)*

New in version 1.7.0.

Set the size of the receive (SO_RCVBUF) and send (SO_SNDBUF) buffers for incoming UDP sockets. On Linux the default values correspond to `net.core.rmem_default` and `net.core.wmem_default`, and the maximum values are restricted by `net.core.rmem_max` and `net.core.wmem_max`.

**Parameters**

- **recv** *(int)* – SO_RCVBUF value. Default is 0, meaning the system value will be kept.
- **send** *(int)* – SO_SNDBUF value. Default is 0, meaning the system value will be kept.

**setUDPTimeout** *(num)*

Set the maximum time dnsdist will wait for a response from a backend over UDP, in seconds. Defaults to 2

**Parameters**

- **num** *(int)* –
19.22 Key Value Store functions and objects

These are all the functions, objects and methods related to the CDB and LMDB key value stores.

A lookup into a key value store can be done via the `KeyValueStoreLookupRule()` rule or the `KeyValueStoreLookupAction()` action, using the usual selectors to match the incoming queries for which the lookup should be done.

The first step is to get a `KeyValueStore` object via one of the following functions:

- `newCDBKVStore()` for a CDB database;
- `newLMDBKVStore()` for a LMDB one.

Then the key used for the lookup can be selected via one of the following functions:

- the exact qname with `KeyValueLookupKeyQName()`;
- a suffix match via `KeyValueLookupKeySuffix()`, meaning that several lookups will be done, removing one label from the qname at a time, until a match has been found or there is no label left;
- the source IP, in network byte order, with `KeyValueLookupKeySourceIP()`;
- the value of an existing tag with `KeyValueLookupKeyTag()`.

For example, to do a suffix-based lookup into a LMDB KVS database, the following rule can be used:

```plaintext
> kvs = newLMDBKVStore('/path/to/lmdb/database', 'database name')
> addAction(AllRule(), KeyValueStoreLookupAction(kvs, KeyValueLookupKeySuffix(), 'kvs-suffix-result'))
```

For a query whose qname is “sub.domain.powerdns.com.”, and for which only the “\8powerdns\3com\0” key exists in the database, this would result in the following lookups:

- \3sub\6domain\8powerdns\3com\0
- \6domain\8powerdns\3com\0
- \8powerdns\3com\0

Then a match is found for the last key, and the corresponding value is stored into the ‘kvs-suffix-result’ tag. This tag can now be used in subsequent rules to take an action based on the result of the lookup. Note that the tag is also created when the key has not been found, but the content of the tag is empty.

```plaintext
> addAction(TagRule('kvs-suffix-result', 'this is the value obtained from the lookup'), SpoofAction('2001:db8::1'))
```

If the value found in the LMDB database for the key ‘\8powerdns\3com\0’ was ‘this is the value obtained from the lookup’, then the query is immediately answered with a AAAA record.

```plaintext
class KeyValueStore

New in version 1.4.0.

Represents a Key Value Store:

:lookup (key[, wireFormat])

Does a lookup into the corresponding key value store, and return the result as a string. The key can be a `ComboAddress` obtained via the `newCA()`, a `DNSName` obtained via the `newDNSName()` function, or a raw string.

Parameters

- DNSName or string key (ComboAddress, ) – The key to look up
- wireFormat (bool) – If the key is DNSName, whether to use to do the lookup in wire format (default) or in plain text
```
**lookupSuffix** *(key, minLabels, wireFormat)*

Does a suffix-based lookup into the corresponding key value store, and return the result as a string. The key should be a DNSName object obtained via the `newDNSName()` function, and several lookups will be done, removing one label from the name at a time until a match has been found or there is no label left. If minLabels is set to a value larger than 0 the lookup will only be done as long as there is at least minLabels remaining. For example if the initial domain is “sub.powerdns.com.” and minLabels is set to 2, lookups will only be done for “sub.powerdns.com.” and “powerdns.com.”.

**Parameters**
- **key** (DNSName) – The name to look up
- **minLabels** (int) – The minimum number of labels to do a lookup for. Default is 0 which means unlimited
- **wireFormat** (bool) – Whether to do the lookup in wire format (default) or in plain text

**reload()**

Reload the database if this is supported by the underlying store. As of 1.4.0, only CDB stores can be reloaded, and this method is a no-op for LMDB stores.

**KeyValueLookupKeyQName** *(wireFormat)* → KeyValueLookupKey

New in version 1.4.0.

Return a new KeyValueLookupKey object that, when passed to `KeyValueStoreLookupAction()` or `KeyValueStoreLookupRule()`, will return the qname of the query in DNS wire format.

**Parameters**
- **wireFormat** (bool) – Whether to do the lookup in wire format (default) or in plain text

**KeyValueLookupKeySourceIP** *(v4mask, v6mask)* → KeyValueLookupKey

New in version 1.4.0.

Changed in version 1.5.0: Optional parameters v4mask and v6mask added.

Changed in version 1.7.0: Optional parameter includePort added.

Return a new KeyValueLookupKey object that, when passed to `KeyValueStoreLookupAction()` or `KeyValueStoreLookupRule()`, will return the source IP of the client in network byte-order.

**Parameters**
- **v4mask** (int) – Mask applied to IPv4 addresses. Default is 32 (the whole address)
- **v6mask** (int) – Mask applied to IPv6 addresses. Default is 128 (the whole address)
- **includePort** (int) – Whether to append the port (in network byte-order) after the address. Default is false

**KeyValueLookupKeySuffix** *(minLabels, wireFormat)* → KeyValueLookupKey

New in version 1.4.0.

Return a new KeyValueLookupKey object that, when passed to `KeyValueStoreLookupAction()` or `KeyValueStoreLookupRule()`, will return a vector of keys based on the labels of the qname in DNS wire format or plain text. For example if the qname is sub.domain.powerdns.com. the following keys will be returned:

- \3sub\6domain\8powerdns\3com\0
- \6domain\8powerdns\3com\0
- \8powerdns\3com\0
- \3com\0
- \0

---

19.22. Key Value Store functions and objects
If minLabels is set to a value larger than 0 the lookup will only be done as long as there is at least minLabels remaining. Taking back our previous example, it means only the following keys will be returned if minLabels is set to 2:

- \3sub\6domain\8powerdns\3com\0
- \6domain\8powerdns\3com\0
- \8powerdns\3com\0

### Parameters

- **minLabels** *(int)* – The minimum number of labels to do a lookup for. Default is 0 which means unlimited
- **wireFormat** *(bool)* – Whether to do the lookup in wire format (default) or in plain text

### KeyValueLookupKeyTag

```
(tagName) → KeyValueLookupKey
```

New in version 1.4.0.

Return a new KeyValueLookupKey object that, when passed to `KeyValueStoreLookupAction()`, will return the value of the corresponding tag for this query, if it exists.

### Parameters

- **tagName** *(str)* – The name of the tag.

### newCDBKVStore

```
(filename, refreshDelay) → KeyValueStore
```

New in version 1.4.0.

Return a new KeyValueStore object associated to the corresponding CDB database. The modification time of the CDB file will be checked every ‘refreshDelay’ second and the database re-opened if needed.

### Parameters

- **filename** *(string)* – The path to an existing CDB database
- **refreshDelays** *(int)* – The delay in seconds between two checks of the database modification time. 0 means disabled

### newLMDBKVStore

```
(filename, dbName[, noLock]) → KeyValueStore
```

New in version 1.4.0.

Changed in version 1.7.0: Added the optional parameter noLock.

Return a new KeyValueStore object associated to the corresponding LMDB database. The database must have been created with the MDB_NOSUBDIR flag. Since 1.7.0, the database is opened with theMDB_READONLY flag, and optionally with MDB_NOLOCK if noLock is set to true.

### Parameters

- **filename** *(string)* – The path to an existing LMDB database created with MDB_NOSUBDIR
- **dbName** *(string)* – The name of the database to use
- **noLock** *(bool)* – Whether to open the database with the MDB_NOLOCK flag. Default is false

## 19.23 Logging

There are some functions to create log output.

### errlog

```
(line)
```

Writes a error line.

### Parameters

- **line** *(str)* – The line to write.
warnlog\( (\text{line}) \)  
Writes a warning line.

Parameters \text{line} (str) – The line to write.

infolog\( (\text{line}) \)  
 Writes an info line.

Parameters \text{line} (str) – The line to write.

vinfo\( \text{log} (\text{line}) \)  
New in version 1.8.0.
 Writes an info line if dnsdist is running in verbose (debug) mode.

Parameters \text{line} (str) – The line to write.

19.24 Webserver-related objects

class WebRequest  
Represent a HTTP query, whose attributes are read-only.

body  
The body of this query, as a string.

getvars  
The GET parameters of this query, as a table whose keys and values are strings.

headers  
The HTTP headers of this query, as a table whose keys and values are strings.

method  
The method of this query, as a string.

path  
The path of this query, as a string.

postvars  
The POST parameters of this query, as a table whose keys and values are strings.

version  
The HTTP version of this query, as an integer.

class WebResponse  
Represent a HTTP response.

body  
The body of this response, as a string.

headers  
The HTTP headers of this response, as a table whose keys and values are strings.

status  
The HTTP status code of this response, as an integer.

19.25 SVCRecordParameters

newSVCRecordParameters (priority, target[, SVCParams]) \rightarrow\ SVCRecordParameters  
New in version 1.7.0.

Returns a \text{SVCRecordParameters} to use with \text{ SpoofSVCAction()}. 

Parameters

- **priority** (int) – The priority of this record. if more than one record is returned, they all should have different priorities. A priority of 0 indicates Alias mode and no other record should be present in the RRSet.

- **target** (str) – A domain name indicating the target name.

- **SVCParams** (table) – Optional table of additional parameters. The key should be the name of the SVC parameter and will be used as the SvcParamKey, while the value depends on the key (see below)

These SVCParams can be set:

```lua
{  
  mandatory={STRING}, -- The mandatory keys. the table of strings must be
  -- the keys names (like "port" and "key998").
  alpn={STRING}, -- alpns for this record, like "dot" or "h2".
  noDefaultAlpn=BOOL, -- When true, the no-default-alpn key is included in
  -- the record, false or absent means it does not exist in the record.
  port=NUM, -- Port parameter to include.
  ipv4hint={STRING}, -- IPv4 hints to include into the record.
  ech=STRING, -- Encrypted Client Hello as a raw string (can include
  -- null bytes).
  ipv6hint={STRING} -- IPv6 hints to include into the record.
}
```

Any other parameters can be set by using the keyNNNN syntax and must use a raw string. Like this:

```
key776="hello\0world"
```

**class SVCRecordParameters**

New in version 1.7.0.

Represents Service Binding (SVCB, HTTPS) record parameters, which can be used with `SpoofSVCAction()`.

### 19.26 Custom Metrics

You can define your own metrics that can be updated using Lua.

The first step is to declare a new metric using `declareMetric()`. In 1.8.0 the declaration had to be done at configuration time, but since 1.8.1 it can be done at any point.
Then you can update those at runtime using the following functions, depending on the metric type:

- manipulate counters using `incMetric()` and `decMetric()`
- update a gauge using `setMetric()`

`declareMetric` *(name, type, description[, prometheusName]) → bool*

New in version 1.8.0.

Changed in version 1.8.1: This function can now be used at runtime, instead of only at configuration time.

Return true if declaration was successful

**Parameters**

- `name` *(str)* – The name of the metric, lowercase alphanumerical characters and dashes (-) only
- `type` *(str)* – The desired type in `gauge` or `counter`
- `name` – The description of the metric
- `prometheusName` *(str)* – The name to use in the prometheus metrics, if supplied. Otherwise the regular name will be used, prefixed with `dnsdist_` and `-` replaced by `_`.

`incMetric` *(name[, step]) → int*

New in version 1.8.0.

Changed in version 1.8.1: Optional `step` parameter added.

Increment counter by one (or more, see the `step` parameter), will issue an error if the metric is not declared or not a `counter`

Return the new value

**Parameters**

- `name` *(str)* – The name of the metric
- `step` *(int)* – By how much the counter should be incremented, default to 1.

`decMetric` *(name) → int*

New in version 1.8.0.

Changed in version 1.8.1: Optional `step` parameter added.

Decrement counter by one (or more, see the `step` parameter), will issue an error if the metric is not declared or not a `counter`

Return the new value

**Parameters**

- `name` *(str)* – The name of the metric
- `step` *(int)* – By how much the counter should be decremented, default to 1.

`getMetric` *(name) → double*

New in version 1.8.0.

Get metric value

**Parameters**

- `name` *(str)* – The name of the metric

`setMetric` *(name, value) → double*

New in version 1.8.0.

Set the new value, will issue an error if the metric is not declared or not a `gauge`

Return the new value

**Parameters**

- `name` *(str)* – The name of the metric
- `value` *(double)* – The new value
20.1 dnsdist

20.1.1 Synopsis

dnsdist [option...] [address]...

20.1.2 Description

dnsdist receives DNS queries and relays them to one or more downstream servers. It subsequently sends back responses to the original requestor.

dnsdist operates over TCP and UDP, and strives to deliver very high performance over both.

Currently, queries are sent to the downstream server with the least outstanding queries. This effectively implies load balancing, making sure that slower servers get less queries.

If a reply has not come in after a few seconds, it is removed from the queue, but in the short term, timeouts do cause a server to get less traffic.

IPv4 and IPv6 operation can be mixed and matched, in other words, queries coming in over IPv6 could be forwarded to IPv4 and vice versa.

dnsdist is scriptable in Lua, see the dnsdist documentation for more information on this.

20.1.3 Scope

dnsdist does not ‘think’ about DNS queries, it restricts itself to measuring response times and error codes and routing questions accordingly. It comes with a very high performance packet-cache.

The goal for dnsdist is to remain simple. If more powerful loadbalancing is required, dedicated hardware or software is recommended. Linux Virtual Server for example is often mentioned.

20.1.4 Options

- -a <netmask>, --acl <netmask>    Add netmask to the ACL.
- -C <file>, --config <file>     Load configuration from file.
- --check-config     Test the configuration file (which may be set with --config or -C) for errors. dnsdist will show the errors and exit with a non-zero exit-code when errors are found.
- -c <address>, --client <address>     Operate as a client, connect to dnsdist. This will read the dnsdist configuration for the controlSocket statement and connect to it. When address (with an optional port number) is set, dnsdist will connect to that instead.
-k <key>, --setkey <key>  When operating as a client(-c, --client), use key as shared secret to connect to dnsdist. This should be the same key that is used on the server (set with setKey()). Note that this will leak the key into your shell’s history and into the systems running process list. Only available when dnsdist is compiled with libsodium or libcrypto support.

-e, --execute <command>  Connect to dnsdist and execute command.

-h, --help  Display a helpful message and exit.

-l, --local <address>  Bind to address. Supply as many addresses (using multiple --local statements) to listen on as required. Specify IPv4 as 0.0.0.0:53 and IPv6 as :::53.

--supervised  Run in foreground, but do not spawn a console. Use this switch to run dnsdist inside a supervisor (use with e.g. systemd and daemontools).

--disable-syslog  Disable logging to syslog. Use this when running inside a supervisor that handles logging (like systemd).

--log-timestamps  Prepend timestamps to messages logged to standard out.

-u, --uid <uid>  Change the process user to uid after binding sockets. uid can be a name or number.

-g, --gid <gid>  Change the process group to gid after binding sockets. gid Can be a name or number.

-V, --version  Show the dnsdist version and exit.

-v, --verbose  Be verbose.

address are any number of downstream DNS servers, in the same syntax as used with --local. If the port is not specified, 53 is used.

20.1.5 Bugs

Right now, the TCP support has some rather arbitrary limits.

20.1.6 Resources

Website: https://dnsdist.org
21.1 1.8.3

Released: 15th of December 2023

Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.1.1 Improvements

• Add a DynBlockRulesGroup:removeRange() binding References: pull request 13601
• Add a DNSHeader:getTC() Lua binding References: pull request 13605

21.1.2 Bug Fixes

• Fix code producing JSON References: #13050, pull request 13607
• Refactor the exponential back-off timer code References: #13519, pull request 13523
• Detect and dismiss truncated UDP responses from a backend References: pull request 13598
• Fix the removal of the last rule by name or UUID References: pull request 13599
• Fix several cosmetic issues in eBPF dynamic blocks, update documentation References: #13307, pull request 13602

21.2 1.9.0-alpha4

Released: 14th of December 2023

Please review the Upgrade Guide before upgrading.

21.2.1 New Features

• Add support for incoming DNS over HTTP/3 References: pull request 13556
• Add a ‘rings’ endpoint to the REST API References: pull request 13489
• Add support for setting Extended DNS Error statuses References: pull request 13473
• Add a cache-miss ratio dynamic block rule References: pull request 13492
• Add getAddressInfo() for asynchronous DNS resolution References: pull request 13505
• Add PayloadSizeRule and TCResponseAction References: pull request 13564
21.2.2  Improvements

- Require Quiche >= 0.15.0 [References: pull request 13437]
- Add missing DoQ latency metrics [References: pull request 13472]
- Send a HTTP 400 response to HTTP/1.1 clients [References: pull request 13594]
- Remove legacy terms from the codebase (Kees Monshouwer) [References: pull request 13023]
- Wrap DIR* objects in unique pointers to prevent memory leaks [References: pull request 13191]
- Add a DynBlockRulesGroup:removeRange() binding [References: pull request 13342]
- Fix a few Coverity warnings [References: pull request 13435]
- Fix Coverity CID 1523748: Performance inefficiencies in dolog.hh [References: pull request 13445]
- Add pdns::visit_directory(), wrapping opendir/readdir/closedir [References: #13191, pull request 13485]
- Improve NetmaskGroupRule/SuffixMatchNodeRule, deprecate makeRule [References: pull request 13500]
- Add NetmaskGroup:addNMG() to merge Netmask groups [References: pull request 13503]
- Add an option to set the SSL proxy protocol TLV [References: pull request 13506]
- Add Proxy Protocol v2 support to TeeAction [References: pull request 13509]
- Allow setting the action from setSuffixMatchRule{,FFI}()'s visitor [References: pull request 13515]
- Make the max size of entries in the packet cache configurable [References: pull request 13537]
- Spoof a raw response for ANY queries [References: pull request 13560]
- Add Lua FFI bindings: hashing arbitrary data and knowing if the query was received over IPv6 [References: pull request 13565]
- Add QNameSuffixRule [References: pull request 13592]

21.2.3  Bug Fixes

- Fix building with DoQ but without DoH or DoT [References: pull request 13524]
- Fix the case where nghttp2 is available but DoH is disabled [References: pull request 13381]
- Fix the removal of the last rule by name or UUID [References: pull request 13488]
- Refactor the exponential back-off timer code [References: pull request 13520]
- Detect and dismiss truncated UDP responses from a backend [References: pull request 13536]

21.3  1.9.0-alpha3

Released: 20th of October 2023
Please review the Upgrade Guide before upgrading.

21.3.1  New Features

- Add support for incoming DNS over QUIC [References: pull request 13280]
- Log Extended DNS Errors (EDE) to protobuf [References: pull request 13185]
21.3.2 Improvements

- Display the rule name, if any, in the web interface References: pull request 13335
- Add Lua binding to downstream address (Denis Machard) References: #13201, pull request 13275
- Set proper levels when logging messages References: pull request 13305
- Fix several cosmetic issues in eBPF dynamic blocks, update documentation References: pull request 13310

21.3.3 Bug Fixes

- Fix a typo in ‘Client timeouts’ (phonedph1) References: pull request 13302
- Netmask: Normalize subnet masks coming from a string References: pull request 13340
- Prevent DNS header alignment issues References: #13280, pull request 13372

21.3.4 misc

- Fix timeouts on incoming DoH connections with nghttp2 References: pull request 13298
- Enable back h2o support in our packages References: pull request 13274

21.4 1.9.0-alpha2

Released: Never

21.5 1.8.2

Released: 11th of October 2023

This release fixes the HTTP2 rapid reset attack for the packages we provide. If you are compiling DNSdist yourself or using the packages provided by your distribution, please check that the h2o library has been patched to mitigate this vulnerability.

Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.5.1 Bug Fixes

- Switch to our fork of h2o to mitigate the HTTP2 rapid reset attack References: pull request #13349

21.6 1.7.5

Released: 11th of October 2023

This release fixes the HTTP2 rapid reset attack for the packages we provide. If you are compiling DNSdist yourself or using the packages provided by your distribution, please check that the h2o library has been patched to mitigate this vulnerability.

Please review the Upgrade Guide before upgrading from versions < 1.7.x.
21.6.1 Bug Fixes

- Switch to our fork of h2o to mitigate the HTTP2 rapid reset attack
  References: pull request #13351

21.7 1.9.0-alpha1

Released: 18th of September 2023

Please review the Upgrade Guide before upgrading.

21.7.1 New Features

- Add Lua bindings to access selector and action
  References: #13007, pull request 13013
- Add an option to write grepq’s output to a file
  References: pull request 12689

21.7.2 Improvements

- Add support for incoming DoH via nghttp2
  References: pull request 12678
- Add metrics for health-check failures
  References: pull request 13009
- Fix building our fuzzing targets from a dist tarball
  References: pull request 13145
- Add a DNSHeader:getTC() Lua binding
  References: pull request 13135
- Stop passing -u dnsdist -g dnsdist on systemd’s ExecStart
  References: pull request 13088
- Use arc4random only for random values
  References: pull request 12931

21.7.3 Removals

- Change the default for building with net-snmp from auto to no
  References: pull request 13168

21.8 1.8.1

Released: 8th of September 2023

Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.8.1 New Features

- Allow declaring custom metrics at runtime
  References: pull request 13123

21.8.2 Improvements

- Stop using the now deprecated ERR_load_CRYPTO_strings() to detect OpenSSL
  References: pull request 13121
- Automatically load Lua FFI inspection functions
  References: pull request 13122
- Increment the “dyn blocked” counter for eBPF blocks as well
  References: pull request 13125
- Make DNSQType.TSIG available (Jacob Bunk)
  References: pull request 13133
### 21.8.3 Bug Fixes

- Fix a crash when X-Forwarded-For overrides the initial source IP [References: pull request 12977]
- Fix a memory leak when processing TLS tickets w/ OpenSSL 3.x [References: pull request 13130]
- Fix cache hit and miss metrics with DoH queries [References: #12762, pull request 13131]
- Fix a race when creating the first TLS connections [References: pull request 13178]
- Print the received, invalid health-check response ID [References: pull request 12820]
- Account for the health-check run time between two runs [References: pull request 12821]
- Properly set the size of the UDP health-check response [References: pull request 12822]
- Add the query ID to health-check log messages, fix nits [References: pull request 12823]
- Stop setting SO_REUSEADDR on outgoing UDP client sockets [References: pull request 12824]
- Properly handle short reads on backend upgrade discovery [References: pull request 13116]
- Undo an accidentally change of disableZeroScope to disableZeroScoping (Winfried Angele) [References: pull request 13117]
- Fix the group of the dnsdist.conf file when installed via RPM [References: #13027, pull request 13118]
- Work around Red Hat 8 messing up OpenSSL’s headers and refusing to fix it [References: #12926, pull request 13119]
- Fix a typo for libedit in the dnsdist features list [References: pull request 13120]
- Fix webserver config template for our docker container (Houtworm) [References: pull request 13124]
- YaHTTP: Prevent integer overflow on very large chunks [References: pull request 13127]
- Fix the console description of PoolAction and QPSPoolAction (phonedph1) [References: pull request 13128]
- Properly handle reconnection failure for backend UDP sockets [References: #12711, pull request 13129]
- SpoofAction: copy the QClass from the request (Christof Chen) [References: pull request 13132]
- Properly record self-answered UDP responses with recvmsg [References: pull request 13150]

### 21.9 1.7.4

Released: 14th of April 2023

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

#### 21.9.1 New Features

- Add getPoolNames() function, returning a list of pool names (Christof Chen) [References: #12074, pull request 12621]

#### 21.9.2 Bug Fixes

- Skip invalid OCSP files after issuing a warning [References: #12341, pull request 12421]
- Fix the health-check timeout computation for DoH backend [References: pull request 12327]
- Ignore unclean TLS session shutdown [References: #12236, pull request 12237]
- Properly encode json strings containing binary data [References: #9349, pull request 12260]
- Properly update rcode-related metrics on RCodeAction hits [References: #11498, pull request 12484]
• Fix building with boost < 1.56 # References: #12177, pull request 12183
• lock.hh: include <stdexcept> # References: #12453, pull request 12460
• dnsdist-protocols.hh: include <cstdint> (Sander Hoentjen) # References: pull request 12569
• Fix the formatting of ‘showServers’ # References: pull request 12535
• Properly record the incoming flags on a timeout # References: #11905, pull request 12529
• Prevent an underflow of the TCP d_queued counter # References: #12357, pull request 12365
• Properly handle single-SOA XFR responses # References: #12099, pull request 12100
• Also reconnect on ENETUNREACH. (Asgeir Storesund Nilsen) # References: #4155, pull request 11830
• Fix a bug in SetEDNSOptionAction # References: #11728, pull request 11729
• Fix the number of concurrent queries on a backend TCP conn # References: pull request 11718

21.10 1.8.0

Released: 30th of March 2023
Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.10.1 Bug Fixes

• Fix ‘Unknown key’ issue for actions and rules parameters # References: pull request 12687
• Fix a dnsheader unaligned case # References: pull request 12672
• secpoll: explicitly include necessary ctime header for time_t # References: pull request 12654

21.11 1.8.0-rc3

Released: 16th of March 2023
Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.11.1 Improvements

• Report per-incoming transport latencies in the web interface # References: pull request 12638
• Report the TCP latency for TCP-only Do53, DoT and DoH backends # References: pull request 12648
• Count hits in the StatNode # References: pull request 12626

21.11.2 Bug Fixes

• Use the correct source address when harvesting failed # References: pull request 12641
• Fix a race when a cross-protocol query triggers an IO error # References: pull request 12639

21.12 1.8.0-rc2

Released: 9th of March 2023
Please review the Upgrade Guide before upgrading from versions < 1.8.x.
21.12.1 Improvements

- Add Lua bindings for PB requestorID, deviceName and deviceID
  References: pull request 12615
- Clean up the fortify and LTO m4 by not directly editing flags
  References: pull request 12593
- YaHTTP: Better detection of whether C++11 features are available
  References: pull request 12589
- Skip signal-unsafe logging when we are about to exit, with TSAN
  References: pull request 12587

21.12.2 Bug Fixes

- Fix compilation with DoH disabled (Adam Majer)
  References: pull request 12588
- Only increment the ‘servfail-responses’ metric on backend responses (phonedph1)
  References: pull request 12592
- Fix the harvesting of destination addresses
  References: pull request 12586

21.13 1.8.0-rc1

Released: 23rd of February 2023

Please review the Upgrade Guide before upgrading from versions < 1.8.x.

21.13.1 New Features

- Allow randomly selecting a backend UDP socket and query ID
  References: pull request 11163
- Dynamic discovery and upgrade of backends
  References: pull request 11293
- Add support for password protected PKCS12 files for TLS configuration
  References: pull request 11027
- Add experimental support for TLS asynchronous engines
  References: pull request 10734
- Add an API endpoint to remove entries from caches
  References: #10468, #6154, pull request 12473
- Add support for user defined metrics
  References: pull request 11674
- Add the ability to change the qname and owner names in DNS packets
  References: pull request 12417
- Implement async processing of queries and responses
  References: pull request 12388
- Add the ability to cap the TTL of records after insertion into the cache
  References: pull request 12384
- Add SetReducedTTLResponseAction
  References: pull request 12400
- Add a Lua FFI interface for metrics
  References: pull request 12385
- Add a new chain of rules triggered after cache insertion
  References: pull request 12280
- Added XDP middleware for dropped/redirected queries logging (Mini Pierre)
  References: pull request 11020
- Implement a ‘lazy’ health-checking mode
  References: pull request 12065
- Add getPoolNames() function, returning a list of pool names
  (Christof Chen)
  References: #12073, pull request 12074
- Cleaner way of getting the IP/masks associated to a network interface
  References: pull request 12082
- Add Lua helpers to look into the content of DNS payloads
  References: pull request 12022
- Add more Lua bindings for network-related operations
  References: pull request 11994
- Add Lua binding for inspecting the in-memory ring buffers
  References: pull request 12008
• Add Lua bindings to look up domain and IP addresses from the cache References: pull request 12007
• Implement SuffixMatchTree::getBestMatch() to get the name that matched References: pull request 11698
• Use BPF_MAP_TYPE_LPM_TRIE for range matching (Y7n05h) References: pull request 11526
• Add getVerbose() function References: pull request 11637
• Add Lua bindings to access the DNS payload as a string References: pull request 11606
• Add setVerbose() to switch the verbose mode at runtime References: pull request 11567
• Add a ‘getAddressAndPort()’ method to DOHFrontend and TLSFrontend objects References: #11434, pull request 11547
• Add setTCPFastOpenKey() (Y7n05h) References: #9994, pull request 11497
• Add Lua FFI helpers for protocol and MAC address access, proxy protocol payload generation References: pull request 11173
• Add support to store mac address in query rings References: pull request 11184
• Add newThread() function References: pull request 11126
• Lua support to remove resource records from a response References: pull request 11098
• Add support to spoof a full self-generated response from lua References: pull request 11051
• Add a Lua FFI helper to generate proxy protocol payloads References: pull request 10949
• Add Lua bindings to get the list of network interfaces, addresses References: pull request 11017
• Add lua support to limit TTL values of responses References: pull request 11059

21.13.2 Improvements

• Enable experimental kTLS support with OpenSSL on Linux References: pull request 12545
• OpenSSL 3.0: Offer TLS providers as an alternative to TLS engines References: pull request 12423
• Skip invalid OCSP files after issuing a warning References: #12341, pull request 12421
• Gracefully handle a failure to create a TLS server context References: pull request 12435
• Merge the ‘main’ and ‘client’ DoH threads in single acceptor mode References: pull request 12386
• Skip DoT/DoH frontend when a tls configuration error occurs References: pull request 11675
• Faster cache-lookups for DNS over HTTPS queries References: pull request 11901
• Speed up DoH handling by preventing allocations and copies References: pull request 12000
• Only call getsockname() once per incoming DoH connection References: pull request 11851
• More useful default ports for DoT/DoH backends References: pull request 11415
• Libssl: Load only the ciphers and digests needed for TLS, not all of them References: pull request 11166
• Ignore unclean TLS session shutdown References: #12236, pull request 12237
• Add support for metadata in protobuf messages References: pull request 12520
• Improve the scalability of MaxQPSIPRule() References: pull request 12537
• Reduce useless wake-ups from the event loop References: pull request 12276
• Add a ‘single acceptor thread’ build option, reducing the number of threads References: pull request 12003
• Make recording queries/responses in the ringbuffers optional References: pull request 11883
• Slightly reduce contention around a pool’s servers References: pull request 11852
• Set TCP_NODELAY on the TCP connection to backends References: pull request 11734
• Avoid allocating memory in LB policies for small number of servers References: pull request 11689
• SuffixMatchTree: Improve lookup performance References: pull request 11624
• Change dns_tolower() and dns_toupper() to use a table References: pull request 11655
• Scan the UDP buckets only when we have outstanding queries References: #11576, pull request 11577
• Prevent allocations in two corner cases References: pull request 11531
• Only allocate the health-check mplexer when needed References: #11422, pull request 11437
• Defer the actual allocation of the ring buffer entries References: pull request 11171
• Add an option for unauthenticated access to the dashboard References: #10360, pull request 12474
• Add an option for unauthenticated access to the API References: pull request 11514
• Add support for custom prometheus names in custom metrics References: pull request 12553
• Slightly reduce the number of allocations in API calls References: pull request 11987
• Add more detailed metrics References: pull request 11716
• Compute backend latency earlier, to avoid internal latency References: pull request 11707
• Add ‘statistics’ to the general API endpoint References: pull request 11659
• Add a counter for the number of cache cleanups References: pull request 11656
• Enable Link-Time Optimization for our packages References: pull request 12543
• Stop using the deprecated boost::optional::get_value_or References: pull request 12538
• List version number early References: #10932, pull request 12530
• Remove duplicate code in xdp (Y7n05h) References: pull request 12518
• Warn on unsupported parameters (Aki Tuomi) References: pull request 10115
• Add unit tests for the Lua FFI interface References: #12417, pull request 12469
• Refactor ‘cannot be used at runtime’ handling References: pull request 12492
• Fail if we can’t check the configuration file References: #7611, pull request 12481
• Add a configure option to enable LTO References: pull request 12441
• Add a new configure option to initialize automatic variables References: pull request 12427
• Enable FORTIFY_SOURCE=3 when supported by the compiler References: pull request 12381
• Proper accounting of response and cache hits References: pull request 12405
• Support OpenSSL 3.0 for ipcipher CA6 encryption/decryption References: pull request 12411
• Stronger guarantees against data race in the UDP path References: pull request 12383
• Add bindings for the current and query times in DQ/DR References: pull request 12402
• Raise RLIMIT_MEMLOCK automatically when eBPF is requested (Yogesh Singh) References: pull request 11554
• Systemd: Add “After” dependency on time-sync.target (Kevin P. Fleming) References: #11153, pull request 12248
• DNSName constructor use memchr instead of strchr and cleanup with string_view (Axel Viala) References: pull request 11863
• Fix building with boost < 1.56 References: #12142, pull request 12177
• Retain output when expunging from multiple caches (Christof Chen) References: #12075, pull request 12077
• Add build-time options to disable the dynamic blocks and UDP response delay References: pull request 11993
**21.13.3 Bug Fixes**

- Apply the max number of concurrent conns per client to DoH
  References: #12019, pull request 12483
- Fix the health-check timeout computation for DoH backend
  References: pull request 12327
- Fix a crash on a invalid protocol in DoH forwarded-for header
  References: #11604, pull request 11621
- Better handling of multiple carbon servers
  References: #10517, #11216, pull request 12424
- Include `<cstdint>` in `dnsdist-protocols.hh` (Sander Hoentjen)
  References: pull request 12569
- Fix the formatting of ‘showServers’
  References: pull request 12535
- Properly record the incoming flags on a timeout
  References: #11905, pull request 12529
• Properly update rcode-related metrics on RCodeAction hits References: #11498, pull request 12484
• Handle out-of-memory exceptions in the UDP receiver thread References: pull request 12387
• Prevent an underflow of the TCP d_queued counter References: #12357, pull request 12365
• Properly handle single-SOA XFR responses References: #12099, pull request 12100
• Fix a bug in SetEDNSOptionAction References: #11728, pull request 11729
• Also reconnect on ENETUNREACH. (Asgeir Storesund Nilsen) References: #4155, pull request 11830
• Keep retained capabilities even when switching user/group References: pull request 11761
• Fix the number of concurrent queries on a backend TCP conn References: pull request 11718
• Fix invalid proxy protocol payload on a DoH TC to TCP retry References: pull request 11604
• Use the correct outgoing protocol in our ring buffers References: #11501, pull request 11545

21.13.4 Removals

• Remove the leak warning with GnuTLS >= 3.7.3 References: #11201, pull request 11324

21.14 1.7.3

Released: 2nd of November 2022

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

dnsdist 1.7.3 contains no functional changes or bugfixes. This release strictly serves to bring dnsdist packages to our EL9 and Ubuntu Jammy repositories, and upgrades the dnsdist Docker image from Debian buster to Debian bullseye, as buster is officially EOL.

21.14.1 Improvements

• add e9/9stream targets References: pull request 11948
• docker images: upgrade to Debian bullseye References: pull request 11974
• dh_builddeb: force gzip compression (this makes the Ubuntu Jammy packages compatible with our Debian-hosted repositories) References: pull request 11742

21.15 1.7.2

Released: 14th of June 2022

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

21.15.1 Improvements

• Scan the UDP buckets only when we have outstanding queries References: #11576, pull request 11579
• Only allocate the health-check mplexer when needed References: #11422, pull request 11580
• Add Lua bindings to access the DNS payload as a string References: #11606, pull request 11666
21.15.2 Bug Fixes

- Fix invalid proxy protocol payload on a DoH TC to TCP retry
- Fix a crash on an invalid protocol in DoH forwarded-for header
- Add missing descriptions for prometheus metrics

21.16 1.7.1

Released: 25th of April 2022

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

21.16.1 Improvements

- Remove the leak warning with GnuTLS >= 3.7.3
- Fix compilation with OpenSSL 3.0.0
- Docker images: remove capability requirements
- Docker image: install ca-certificates
- Work around a compiler bug seen on OpenBSD/amd64 using clang-13
- Stop using the now deprecated and useless std::binary_function
- Add a `getAddressAndPort()` method to DOHFrontend and TLSFrontend objects

21.16.2 Bug Fixes

- Set Server Name Indication on outgoing TLS connections (DoT, DoH)
- Fix the health-check timeout for outgoing DoH connections
- Fix the latency-count metric
- Fix a use-after-free in case of a network error in the middle of a XFR query
- Properly use eBPF when the DynBlock is not set
- Fix `inConfigCheck()`
- Use the correct outgoing protocol in our ring buffers
- Raise the number of entries in a packet cache to at least 1
- Fix wrong eBPF values (qtype, counter) being inserted for qnames
- The check interval applies to health-check, not timeouts

21.17 1.7.0

Released: 17th of January 2022

Please review the Upgrade Guide before upgrading from versions < 1.7.x.
21.17.1 Bug Fixes

• Test the correct member in DynBlockRatioRule::warningRatioExceeded (Doug Freed) 
  References: #11131, pull request 11156

21.18 1.7.0-rc1

Released: 22nd of December 2021

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

21.18.1 Improvements

• Reuse and save the TLS session tickets in DoT healthchecks 
  References: pull request 11037

21.18.2 Bug Fixes

• Fix a double-free when a DoH cross-protocol response is dropped 
  References: pull request 11075
• Check the size of the query when re-sending a DoH query 
  References: pull request 11079

21.19 1.7.0-beta2

Released: 29th of November 2021

21.19.1 Improvements

• Add a function to know how many TLS sessions are currently cached 
  References: pull request 10997
• Warn that GnuTLS 3.7.x leaks memory when validating certs 
  References: pull request 11001
• Add a function to set the UDP recv/snd buffer sizes 
  References: #10898, pull request 11008
• Add ‘showWebserverConfig’ 
  References: #10135, pull request 11006

21.19.2 Bug Fixes

• Fix a memory leak when reusing TLS tickets for outgoing connections 
  References: pull request 10999
• Fix compiler/static analyzer warnings 
  References: #10988, pull request 10993
• Fix Lua parameters bound checks 
  References: pull request 11007
• Add missing visibility attribute on dnsdist ffi_dnsquestion_get_qname_hash 
  References: pull request 11031

21.20 1.7.0-beta1

Released: 16th of November 2021

Please review the Upgrade Guide before upgrading from versions < 1.7.x.
21.20.1 New Features

- Implement filesystem pinning for eBPF maps, drop and truncate via XDP (Pierre Grié) References: pull request 10498, pull request 10883
- Add range support for dynamic blocks References: #4993, pull request 10815
- Add the ability to retain select capabilities at runtime References: pull request 10923

21.20.2 Improvements

- Read as many DoH responses as possible before yielding References: pull request 10875
- Stop over-allocating for DoH queries References: pull request 10876
- Support DoT, DoH and DNSCrypt transports for protobuf and dnstap References: #9103, pull request 10879
- Use the same outgoing TCP connection for different clients References: pull request 10862
- Convert make_pair to emplace (Rosen Penev) References: pull request 10646
- Add syslog identifier to service file References: #10651, pull request 10795
- Get rid of make_pair (Rosen Penev) References: pull request 10868
- Use make_unique instead of new (Rosen Penev) References: pull request 10870
- Handle existing EDNS content for SetMacAddrAction/SetEDNSOptionAction References: #4670, pull request 10907

21.20.3 Bug Fixes

- Keep watching idle DoH backend connections References: pull request 10845
- Fix the cleaning of TCP, DoT and DoH connections to the backend References: pull request 10920
- Properly handle I/O exceptions in the health checker References: pull request 10874
- NetmaskTree: Drop the ‘noexcept’ qualifier on the TreeNode ctor References: pull request 10900
- Fix build without nghttp2 References: pull request 10922
- Remove debug print line flooding logs (Eugen Mayer) References: pull request 10935
- Credentials: EVP_PKEY_CTX_set1_scrypt_salt() takes an unsigned char* References: #10938, pull request 10943

21.21 1.7.0-alpha2

Released: 19th of October 2021

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

21.21.1 New Features

- Add lua support for SetEDNSOptionAction References: pull request 10814
- Rule for basing decisions on outstanding queries in a pool (phonedph1) References: pull request 10832
21.21.2 Improvements

- Disable TLS renegotiation, release buffers for outgoing TLS References: pull request 10823
- Don’t create SSLKEYLOGFILE files with wide permissions References: pull request 10760
- Update existing tags when calling setTagAction and setTagResponseAction References: pull request 10767
- Fix the unit tests to handle v4-only or v6-only connectivity References: #10403, pull request 10775
- Improve the coverage of the outgoing DoH code References: pull request 10782
- Allow skipping arbitrary EDNS options when computing packet hash References: pull request 10791
- Add incoming and outgoing protocols to grepq References: pull request 10833
- Allow setting the block reason from the SMT callback References: #10559, pull request 10835
- Clear the UDP states of TCP-only backends References: pull request 10844
- Replace shared by unique ptrs, reduce structs size References: pull request 10846

21.21.3 Bug Fixes

- Better handling of outgoing DoH workers References: #10771, pull request 10772
- Properly cache UDP queries passed to a TCP/DoT/DoH backend References: pull request 10787
- Use per-thread credentials for GnuTLS client connections References: pull request 10841
- Only set recursion protection once we know we do not return References: pull request 10848

21.22 1.7.0-alpha1

Released: 23rd of September 2021

Please review the Upgrade Guide before upgrading from versions < 1.7.x.

21.22.1 New Features

- Implementation of DoH between dnsdist and the backend References: pull request 10635
- Implement cross-protocol queries, including outgoing DNS over TLS References: pull request 10338
- Add support for Lua per-thread FFI rules and actions References: pull request 10501
- Add FFI functions to spoof multiple raw values References: #10456, pull request 10532
- Add support for range-based lookups into a Key-Value store References: #10520, pull request 10525
- Implement SpoofSVCAction to return SVC responses References: #10367, pull request 10597

21.22.2 Improvements

- Don’t look up the LMDB dbi by name for every query References: pull request 10520
- Move to hashed passwords for the web interface References: #7937, pull request 10157
- Fix ‘temporary used in loop’ warnings reported by g++ 11.1.0 References: pull request 10429
- Skip some memory allocations in client mode to reduce memory usage References: pull request 10441
- Support multiple ip addresses for dnsdist-resolver lua script (Wim) References: pull request 10414
• Make DNSDist XFR aware when transfer is finished (Dimitrios Mavrommatis) References: #10436, pull request 10489
• Do not report latency metrics of down upstream servers (Holger Hoffstätte) References: #10500, pull request 10508
• Carry the exact incoming protocol (Do53, DNSCrypt, DoT, DoH) in DQ References: #10338, pull request 10537
• Implement ‘reload()’ to rotate Log(Response)Action’s log file References: #10502, pull request 10527
• Document that setECSOverride has its drawbacks (Andreas Jakum) References: pull request 10626
• Convert dnsdist and the recursor to LockGuarded References: pull request 10649
• Handle waiting for a descriptor to become readable OR writable References: pull request 10631
• Clean up a bit of “cast from type […] casts away qualifiers” warnings References: pull request 10687
  Reorganize the IDState and Rings fields to reduce memory usage References: pull request 10381

21.22.3 Bug Fixes

• Catch FDMultiplexerException in IOStateHandler’s destructor References: pull request 10656
• Resizing LMDB map size while there might be open transactions is unsafe References: pull request 10672
• Ignore TCAction over TCP References: #10693, pull request 10695
• Stop raising the number of TCP workers to the number of TCP binds References: pull request 10704
  Handle exception raised in IOStateGuard’s destructor References: pull request 10724

21.23 1.6.1

Released: 15th of September 2021
Please review the Upgrade Guide before upgrading from versions < 1.6.x.

21.23.1 New Features

• Add the missing DOHFronted::loadNewCertificatesAndKeys() References: #10418, pull request 10550
• Implement a web endpoint to get metrics for only one pool References: #10482, pull request 10560

21.23.2 Bug Fixes

• Set the dnstap/protobuf transport to TCP for DoH queries References: #10497, pull request 10538
• Backport a missing mutex header References: pull request 10438
• Properly handle ECS for queries with ancount or nscount > 0 References: #10419, pull request 10619
• Catch FDMultiplexerException in IOStateHandler’s destructor References: pull request 10656
• Fix outstanding counter issue on TCP error References: #10705, pull request 10706

21.24 1.6.0

Released: 11th of May 2021
21.25 1.5.2

Released: 10th of May 2021
Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.25.1 Bug Fixes

• Fix SNI on resumed sessions by acknowledging the name sent by the client
  References: #9921, pull request 9922
• Fix a crash when a DoH responses map is updated at runtime
  References: #9934, pull request 9936
• Fix the DNSName move assignment operator
  References: pull request 9749
• Fix a typo in prometheus metrics dnsdist_frontend_tlshandshakefailures
  References: #9728, pull request 9729
• Make: two fixes
  References: pull request 9583
• Fix eBPF filtering of long qnames
  References: #9689, pull request 9717
• Fix a hang when removing a server with more than one socket
  References: pull request 9900
• Fix Dynamic Block RCode rules messing up the queries count
  References: #9756, pull request 9980
• Fix EDNS in ServFail generated when no server is available
  References: #10006, pull request 10012
• Prevent a crash with DynBPF objects in client mode
  References: #10090, pull request 10095
• Add missing getEDNSOOptions and getDO bindings for DNSResponse
  References: pull request 10355

21.26 1.6.0-rc2

Released: 4th of May 2021
Please review the Upgrade Guide before upgrading from versions < 1.6.x.

21.26.1 Improvements

• Make the backend queryLoad and dropRate values atomic
  References: pull request 10323

21.26.2 Bug Fixes

• Fix missing locks in DNSCrypt certificates management
  References: pull request 10346
• Only use eBPF for “drop” actions, clean up more often
  References: #10324, pull request 10327

21.27 1.6.0-rc1

Released: 20th of April 2021
Please review the Upgrade Guide before upgrading from versions < 1.6.x.
21.27.1 Improvements

• Replace pthread_rwlock with std::shared_mutex \ References: #10209, pull request 10216
• Also disable PMTU for v6 \ References: pull request 10264

21.27.2 Bug Fixes

• Lua: don’t destroy keys during table iteration \ References: pull request 10171
• Add missing getEDNSOptions and getDO bindings for DNSResponse \ References: #10262, pull request 10267
• Fix some issues reported by Thread Sanitizer \ References: pull request 10274

21.28 1.6.0-alpha3

Released: 29th of March 2021

Please review the Upgrade Guide before upgrading from versions < 1.6.x.

21.28.1 Improvements

• Set OpenSSL to release buffers when idle, saves 35 kB per connection \ References: pull request 10179
• Disable TLS renegotiation by default \ References: pull request 10218
• Unify certificate reloading syntaxes \ References: pull request 10214
• Improve TCP connection reuse, add metrics \ References: pull request 10156
• Using DATA to report memory usage is unreliable, start using RES instead, as it seems reliable and relevant \ References: #7591, pull request 10161
• Add a metric for TCP listen queue full events \ References: pull request 10184
• Enable sharding by default, greater pipe buffer sizes \ References: pull request 10204
• Add limits for cached TCP connections, metrics \ References: pull request 10207

21.28.2 Bug Fixes

• Fix the handling of DoH queries with a non-zero ID \ References: pull request 10208
• Fix the TCP connect timeout, add metrics \ References: pull request 10201

21.29 1.6.0-alpha2

Released: 4th of March 2021

Please review the Upgrade Guide before upgrading from versions < 1.6.x.

21.29.1 New Features

• Add option to spoofRawAction to spoof multiple answers (Sander Hoentjen) \ References: pull request 10063
• Add ‘spoof’ and ‘spoofRaw’ Lua bindings \ References: pull request 10073
21.29.2 Improvements

- Make NetmaskTree::fork() a bit easier to understand
  References: #10035, pull request 10046
- Do not update the TCP error counters on idle states
  References: pull request 10131
- Bind __tostring instead of toString for Lua, so that conversion to string works automatically (Aki Tuomi)
  References: pull request 9361

21.29.3 Bug Fixes

- Remove forgotten debug line in the web server
  References: #10049, pull request 10050
- Create TCP worker threads before acceptors ones
  References: pull request 10088
- Prevent a crash with DynBPF objects in client mode
  References: #10090, pull request 10095
- Fix several bugs in the TCP code path, add unit tests
  References: pull request 10108
- Fix size check during trailing data addition, regression tests
  References: pull request 10139
- Clean up expired entries from all the packet cache’s shards
  References: pull request 10133

21.30 1.6.0-alpha1

Released: 2nd of February 2021

Please review the Upgrade Guide before upgrading from versions < 1.6.x.

21.30.1 New Features

- Add per-thread Lua FFI load-balancing policies
  References: pull request 9175
- Implement Lua custom web endpoints
  References: #9120, pull request 9676
- Implement TCP out-of-order
  References: pull request 9582
- Add support for incoming Proxy Protocol
  References: pull request 9616
- Add SkipCacheResponseAction
  References: #9536, pull request 9960

21.30.2 Improvements

- Use more of systemd’s sandboxing options when available
  References: pull request 8969
- Prioritize ChaCha20-Poly1305 when client does (Sukhbir Singh)
  References: pull request 9510
- Add per connection queries count and duration stats for DoH
  References: pull request 9738
- Add an option to allow sub-paths for DoH
  References: pull request 9962
- Start all TCP worker threads on startup
  References: pull request 9957
- Speed up the round robin policy
  References: pull request 9382
- Avoid unnecessary allocations and copies with DNSName::toDNSString()
  References: pull request 9424
- Get rid of allocations in the packet cache’s fast path
  References: #8993, pull request 9420
- Fix the DNSName move assignment operator
  References: pull request 9749
- Don’t copy the policy for every query
  References: pull request 9850
• UUID: Use the non-cryptographic variant of the boost::uuid
References: pull request 9832
• Use an eBPF filter for Dynamic blocks when available
References: #6763, #9756, pull request 9782
• Use protozero for Protocol Buffer operations
References: #9780, #9781, pull request 9843
• Limit the number of concurrent console and web connections
References: #4978, pull request 9997
• Add prometheus metrics for top Dynamic Blocks entries
References: pull request 9756
• Add Lua bindings to get a server’s latency
References: pull request 9273
• Wrap more FILE objects in smart pointers
References: pull request 9225
• Set the default EDNS buffer size on generated answers to 1232
References: pull request 9049
• Add support for FreeBSD’s SO_REUSEPORT_LB
References: #9156, pull request 9157
• Accept string in DNSDistPacketCache:expungeByName
References: pull request 9428
• DNSName: add toStringWithPort convenience function
References: pull request 9466
• Skip EDNS Cookies in the packet cache
References: #5131, pull request 8993
• Add the query payload size to the verbose log over TCP
References: pull request 9677
• Add the response code in the packet cache dump
References: #9274, pull request 9737
• Add an optional name to rules
References: pull request 9746
• Add the ability to set ACL from a file (Matti Hiljanen)
References: pull request 9822
• Add a Lua binding for the number of queries dropped by a server
References: #9861, pull request 9862
• Move to c++17
References: pull request 9913
• Fix warnings on autoconf 2.70
References: #9918, pull request 9920
• Reduce diff to upstream yahttp, fixing a few CodeQL reports
References: pull request 9955
• Handle syslog facility as string, document the numerical one
References: #9383, pull request 9989
• Deprecate parameters to webserver(), add ‘statsRequireAuthentication’ parameter
References: #8710, #9311, pull request 9972
• Add a counter for queries truncated because of a rule
References: #9357, pull request 9992
• Replace offensive terms in our code and documentation
References: pull request 9993
• Use aligned atomics to prevent false sharing
References: #9455, pull request 9998
• Unify non-terminal actions as SetXXXAction()
References: #8118, pull request 9974
• Accept a NMG to fill DynBlockRulesGroup ranges
References: #9545, pull request 10015
• Silence clang 12 warning
References: pull request 10023
• Fix a few warnings reported by clang’s static analyzer and cppcheck
References: pull request 10035

21.30.3 Bug Fixes

• Fix a crash when a DoH responses map is updated at runtime
References: #9927, pull request 9934
• Fix SNI on resumed sessions by acknowledging the name sent by the client
References: pull request 9921
• Use toStringWithPort instead of manual addr/port concat (Mischan Toosarani-Hausberger)
References: #9075, pull request 9222
• Force a reconnection when a downstream transitions to the UP state (Nuitari, Stephane Bakhos)
References: pull request 9275
• Handle EINTR in DelayPipe
References: pull request 9381
• Handle empty DNSNames in grepq()
• Make: two fixes References: pull request 9583
• Fix eBPF filtering of long qnames References: #9626, pull request 9689
• Improve const-correctness of Lua bindings (Georgeto) References: pull request 9721
• Fix a hang when removing a server with more than one socket References: pull request 9900
• Appease clang++ 12 ASAN on macOS References: pull request 9925
• Bunch of signed vs unsigned warnings References: pull request 9937
• Send a NotImp answer on empty (qdcount=0) queries References: #9961, pull request 9991
• Don’t apply QPS to backend server on cache hits References: #7038, pull request 9999
• Fix EDNS in ServFail generated when no server is available References: #10006, pull request 10012

21.30.4 Removals

• Rename topRule() and friends References: pull request 9532
• Remove useless second argument for SpoofAction References: #9783, pull request 9784

21.31 1.5.1

Released: 1st of October 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.31.1 Improvements

• Add the ‘clearConsoleHistory’ command References: #9372, pull request 9540

21.31.2 Bug Fixes

• Stop the related responder thread when a backend is removed References: #9372, pull request 9541
• Fix getEDNSOptions() for (AN,NS) COUNT != 0 and ARCOUNT = 0 References: pull request 9542
• Fix building with LLVM11 (@RvdE) References: pull request 9543
• Only add EDNS on negative answers if the query had EDNS References: pull request 9555

21.32 1.5.0

Released: 30th of July 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.32.1 Improvements

• Use explicit flag for the specific version of c++ we are targeting. References: pull request 9231
• Prevent a copy of a pool’s backends when selecting a server. References: pull request 9360
21.32.2 Bug Fixes

- Fix compilation with h2o_socket_get_ssl_server_name(). References: pull request 9344
- Prevent a possible overflow via large Proxy Protocol values. (Valentei Sergey) References: pull request 9320
- Avoid name clashes on Solaris derived systems. References: #9279, pull request 9348
- Resize hostname to final size in getCarbonHostname(). (Aki Tuomi) References: pull request 9343
- Fix compilation on OpenBSD/amd64. References: pull request 9346
- Handle calling PacketCache methods on a nil object. References: pull request 9356

21.33 1.5.0-rc4

Released: 7th of July 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.33.1 Bug Fixes

- Prevent a race between the DoH handling threads. References: pull request 9278

21.34 1.5.0-rc3

Released: 18th of June 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.34.1 New Features

- Implement an ACL in the internal web server. References: pull request 9229

21.34.2 Improvements

- Less negatives in secpoll error messages improves readability. References: pull request 9100
- Use std::string_view when available (Rosen Penev) References: pull request 9207
- Clean up dnsdistconf.lua as a default configuration file. References: #8038, pull request 9238
- Add optional masks to KeyValueLookupKeySourceIP. References: pull request 9244

21.34.3 Bug Fixes

- Use non-blocking pipes to pass DoH queries/responses around. References: #9206, pull request 9211
- Fix compilation on systems that do not define HOST_NAME_MAX. References: #9125, pull request 9127
- Do not use using namespace std. References: pull request 9213
21.35 1.5.0-rc2

Released: 13th of May 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.35.1 Improvements

- Add the unit to the help for latency buckets References: pull request 9084
- Avoid copies in for loops References: pull request 9042
- Build with -Wmissing-declarations -Wredundant-decls References: pull request 9054
- Use std::shuffle instead of std::random_shuffle References: #9004, pull request 9016
- Get rid of a naked pointer in the /dev/poll event multiplexer References: pull request 9053
- A few warnings fixed, reported by clang on OpenBSD References: pull request 9059
- Wrap pthread objects References: pull request 9067
- NetmaskTree: do not test node for null, the loop guarantees node is not null. References: pull request 9078

21.35.2 Bug Fixes

- Fix duplicated HTTP/1 counter in `showDOHFrontends()` References: pull request 9068
- Fix compilation of the ports event multiplexer References: #9025, pull request 9031
- Gracefully handle a failure to remove FD on (re)-connection References: pull request 9057

21.36 1.5.0-rc1

Released: 16th of April 2020

Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.36.1 Improvements

- Expose SuffixMatchNode::remove in Lua References: pull request 8956
- Remove a std::move() preventing Return-Value Optimization in lmdb-safe.cc References: pull request 8962
- Drop responses with the QR bit set to 0 References: pull request 8996
- Add an option to control the size of the TCP listen queue References: #8986, pull request 8994

21.36.2 Bug Fixes

- Keep accepting fragmented UDP datagrams on DNSCrypt binds References: pull request 8974
- Accept UDP datagrams larger than 1500 bytes for DNSCrypt References: #8974, pull request 8976
- On OpenBSD string_view is both in boost and std References: pull request 8955
21.37  1.5.0-alpha1

Released: 20th of March 2020
Please review the Upgrade Guide before upgrading from versions < 1.5.x.

21.37.1 New Features

- Implement LuaFFIRule, LuaFFIAction and LuaFFIResponseAction References: #7617, pull request 8505
- Add SetNegativeAndSOAAction() and its Lua binding References: #4747, pull request 8171
- Implement dynamic blocking on ratio of rcode/total responses References: pull request 8274
- Add bounded loads to the consistent hashing policy References: #7387, pull request 8567
- LogResponseAction (phonedph1) References: pull request 8654
- Add spoofRawAction() to craft answers from raw bytes References: pull request 8722
- Add support for Proxy Protocol between dnsdist and the recursor References: pull request 8874
- Implement bounded loads for the whashed and wrandom policies References: pull request 8909

21.37.2 Improvements

- Don’t accept sub-paths of configured DoH URLs References: #8573, pull request 8760
- Implement Cache-Control headers in DoH References: #8586, pull request 8762
- Document that the ‘keyLogFile’ option requires OpenSSL >= 1.1.1 References: #8806, pull request 8899
- Change the default DoH path from / to /dns-query References: #8819, pull request 8905
- Add support for the processing of X-Forwarded-For headers References: #8661, pull request 8945
- Switch the default DoT provider from GnuTLS to OpenSSL References: pull request 8380
- Add the source and destination ports to the protobuf msg References: pull request 8702
- Better handling of reconnections in Remote Logger References: pull request 8887
- Rework NetmaskTree for better CPU and memory efficiency. (Stephan Bosch) References: pull request 8355
- Implement parallel health checks References: pull request 8491
- Use move semantics when updating the content of the StateHolder References: pull request 8538
- Keep a masked network in the Netmask class References: pull request 8812
- Make FrameStream IO parameters configurable References: pull request 8937
- Add backend status to prometheus metrics References: #8746, pull request 8772
- Add ‘IO wait’ and ‘steal’ metrics on Linux References: pull request 8783
- Don’t start as root within a systemd environment References: pull request 7820
- Separate the check-config and client modes References: pull request 8456
- Add the number of received bytes to StatNode entries References: pull request 8529
- Support setting the value of AA, AD and RA when self-generating answers References: #8534, pull request 8556
- pthread_rwlock_init() should be matched by pthread_rwlock_destroy() References: pull request 8580
- Replace include guard ifdef/define with pragma once (Chris Hofstaedtler) References: pull request 8631
• Allow retrieving and deleting a backend via its UUID References: pull request 8657
• Load an openssl configuration file, if any, during startup References: pull request 8733
• Add get*BindCount() functions References: pull request 8848
• Add sessionTimeout setting for TLS session lifetime (Matti Hiljanen) References: pull request 8882
• Detect {Libre,Open}SSL functions availability during configure References: #8739, pull request 8900
• Warn on startup about low weight values with chashed References: #8669, pull request 8950

21.37.3 Bug Fixes

• Set the DoH ticket rotation delay before loading tickets References: pull request 8949
• Display the correct DoT provider References: pull request 8662
• Use ref counting for the DoT TLS context References: pull request 8761
• Add ‘queue full’ metrics for our remote logger, log at debug only References: #8629, pull request 8883
• Fix ECS addition when the OPT record is not the last one References: #8098, pull request 8115
• Wait longer for the TLS ticket to arrive in our tests References: pull request 8591
• Add missing exception message in KVS error References: pull request 8604
• Add getTag()/setTag() Lua bindings for a DNSResponse References: pull request 8782
• Fix key logging for DNS over TLS References: #8442, pull request 8878
• Fix a typo in the help/completion for getDNSCryptBindCount References: pull request 8855
• Implement rmACL() (swoga) References: pull request 8856
• Remove unused lambda capture reported by clang++ References: pull request 8879

21.38 1.4.0

Released: 20th of November 2019
Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.38.1 Improvements

• Fix the default value of setMaxUDPOutstanding in the console’s help (phonedph1) References: pull request 8531
• Add bindings for the noerrors and drops members of StatNode References: pull request 8522
• Fix -Wshadow warnings (Aki Tuomi) References: pull request 8440
• Fix typo: settting to setting (Chris Hofstaedtler) References: pull request 8509

21.38.2 Bug Fixes

• Lowercase the name blocked by a SMT dynamic block References: pull request 8524

21.38.3 misc

• Prefer the cipher suite from the server by default (DoH, DoT) References: pull request 8526
21.39 1.4.0-rc5

Released: 30th of October 2019
Please review the *Upgrade Guide* before upgrading from versions < 1.4.x.

21.39.1 Improvements

- Rename the ‘address’ label to ‘frontend’ for DoH metrics \[ References: pull request 8465 \]

21.39.2 Bug Fixes

- Increment the DOHUnit ref count when it’s set in the IDState \[ References: pull request 8471 \]

21.40 1.4.0-rc4

Released: 25th of October 2019
Please review the *Upgrade Guide* before upgrading from versions < 1.4.x.

21.40.1 New Features

- Add support dumping TLS keys via keyLogFile \[ References: pull request 8442 \]

21.40.2 Improvements

- Implement reference counting for the DOHUnit object \[ References: pull request 8416 \]
- Add metrics about TLS handshake failures for DoH and DoT \[ References: pull request 8447 \]
- Merge the setup of TLS contexts in DoH and DoT \[ References: pull request 8383 \]
- Add metrics about unknown/inactive TLS ticket keys \[ References: pull request 8406 \]
- Count the number of concurrent connections for DoH as well \[ References: pull request 8395 \]
- Add a ‘preferServerCiphers’ option for DoH and DoT \[ References: pull request 8382 \]
- Lowercase custom DoH header names \[ References: #8353, pull request 8365 \]
- Refactor DoH prometheus metrics again \[ References: pull request 8361 \]
- Add metrics about TLS versions with DNS over TLS \[ References: pull request 8387 \]
- Add more options to LogAction (non-verbose mode, timestamps) \[ References: #8390, pull request 8411 \]
- Fix formatting in showTCPStats() \[ References: pull request 8415 \]
- Use SO_BINDTODEVICE when available for newServer’s source interface \[ References: pull request 8372 \]
- Check the address supplied to ‘webserver’ in check-config \[ References: #8362, pull request 8364 \]
21.40.3 Bug Fixes

- Clear the DoH session ticket encryption key in the ctor References: pull request 8388
- Add missing prometheus descriptions for cache-related metrics References: pull request 8409
- Add a prometheus ‘thread’ label to distinguish identical frontends References: pull request 8381
- Fix a typo in the prometheus description of ‘senderrors’ References: pull request 8378
- More prometheus fixes References: pull request 8368
- Fix the caching of large entries References: pull request 8408
- Work around cmsg_space somehow not being a constexpr on macOS References: #8412, pull request 8413
- Fix the creation order of rules when inserted via setRules() References: pull request 8359

21.41 1.4.0-rc3

Released: 30th of September 2019
Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.41.1 Improvements

- Display the DoH and DoT binds in the web view References: pull request 8264
- Allow accepting DoH queries over HTTP instead of HTTPS References: pull request 8267
- Implement TLS session ticket keys management for DoH References: pull request 8349
- Clean up our interactions with errno References: #7845, pull request 8083
- Remove the ‘blockfilter’ stat from the web view References: #5514, pull request 8265
- Fix some spelling mistakes noticed by lintian (Chris Hofstaedtler) References: pull request 8268
- dnsdistconf.lua use non-deprecated versions for 1.4.0 (phonedph1) References: pull request 8285
- Better use of labels in our DoH prometheus export References: pull request 8318

21.41.2 Bug Fixes

- Fix the newCDBKVStore console completion when LMDB is not enabled (phonedph1) References: pull request 8281
- Allow configure CDB_CFLAGS to work (phonedph1) References: pull request 8283
- Fix the warning message on an invalid secpoll answer References: pull request 8303
- Don’t connect to remote logger in client/command mode References: #8300, pull request 8304

21.42 1.4.0-rc2

Released: 2nd of September 2019
Please review the Upgrade Guide before upgrading from versions < 1.4.x.
21.42.1 New Features

- Add support for early DoH HTTP responses References: pull request 8206
- Add a KeyValueStoreLookup action based on CDB or LMDB References: pull request 8139

21.42.2 Improvements

- Add minTLSVersion for DoH and DoT References: #8202, pull request 8207
- Split dnsdist-lua-bindings.cc to reduce memory consumption during compilation References: pull request 8250
- Add a Lua binding for dynBlockRulesGroup:setQuiet(quiet) References: pull request 8252

21.42.3 misc

- Update h2o to 2.2.6, fixing CVE-2019-9512, CVE-2019-9514 and CVE-2019-9515 for repo.powerdns.com packages References: pull request 8200

21.43 1.4.0-rc1

Released: 12th of August 2019

Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.43.1 New Features

- Add OCSP stapling (from files) for DoT and DoH References: #7812, pull request 8141
- Add support for custom DoH headers (Melissa Voegeli) References: #7900, #7957, pull request 8148
- Add lua bindings, rules and action for DoH References: #8133, pull request 8153
- Implement ContinueAction() References: pull request 8117

21.43.2 Improvements

- Send better HTTP status codes, handle ACL drops earlier References: pull request 7917
- Add more stats about DoH HTTP responses References: #7898, pull request 7933
- Improve error messages for DoT issues References: pull request 7978
- Accept more than one certificate in addDNSCryptBind() References: #8020, pull request 8042
- Disallow TCP disablement References: pull request 7860
- Update boost.m4 to the latest version References: pull request 7862
- Print stats from expungeByName (Matti Hiljanen) References: pull request 7909
- Squeelch unused function warning References: #7950, pull request 7952
- SuffixMatchNode:add(): accept more types References: pull request 7985
- Explicitly align the buffer used for cmsgs References: #7980, pull request 7990
- Add quiet parameter to NetmaskGroupRule References: pull request 7992
- Clear cmsg_space(sizeof(data)) in cmsghdr to appease Valgrind References: #7981, pull request 7996
• Add static assertions for the size of the src address control buffer References: pull request 8007
• Don’t create temporary strings to escape DNSName labels References: pull request 8013
• Display TCP/DoT queries and responses in verbose mode, opcode in grepq References: pull request 8024
• Be a bit more explicit about what failed in testCrypto() References: pull request 8025
• Update URLs to use HTTPS scheme (Chris Hofstaedtler) References: pull request 8110
• Double-check we only increment the outstanding counter once References: pull request 8113
• ext/ipcrypt: ship license in tarballs (Chris Hofstaedtler) References: #8108, pull request 8135
• Use a counter to mark IDState usage instead of the FD References: pull request 8154
• Increase the default value of setMaxUDPOutstanding to 65535 References: pull request 8175

21.43.3 Bug Fixes

• Properly override the HTTP Server header for DoH References: #7894, pull request 7911
• Exit when requested DoT/DoH support is not compiled in References: pull request 7915
• Proper HTTP response for timeouts over DoH References: #7917, pull request 7927
• Prevent a dangling DOHUnit pointer when send() failed References: pull request 8112
• Skip non-dnscrypt binds in showDNSCryptBinds() References: #8014, pull request 8015
• SuffixMatchTree: fix root removal, partial match of non-leaf nodes References: pull request 7886
• Deduplicate frontends entries with carbon and prometheus References: #7933, pull request 7934
• Update boost.m4 References: #6942, #8084, pull request 7951
• Fix short IOs over TCP References: #7971, pull request 7974
• Fix handling of backend connection failing over TCP References: pull request 7979
• Insert the response into the ringbuffer right after sending it References: pull request 8003
• Handle ENOTCONN on read() over TCP References: #8021, pull request 8030
• Make sure we always compile with BOOST_CB_ENABLE_DEBUG set to 0 References: pull request 8067
• Catch exceptions thrown when handling a TCP response References: pull request 8078
• Fix unlimited retries when TCP Fast Open is enabled References: pull request 8079
• M4/systemd.m4: fail when systemctl is not available References: pull request 8081
• Fix a typo in the Server’s latency description for Prometheus (phonedph1) References: pull request 8105
• Console: flush cout after printing g_outputbuffer (Doug Freed) References: #8130, pull request 8131
• Fix signedness issue in isEDNSOptionInOpt() References: pull request 8158

21.44 1.4.0-beta1

Released: 6th of June 2019
Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.44.1 New Features

• Implement SNIRule for DoT and DoH References: #7210, pull request 7825
21.44.2 Improvements

- Support Prometheus latency histograms (Marlin Cremers) References: #6088, pull request 7853

21.44.3 Bug Fixes

- DoH: Don’t let ‘self’ dangling while parsing the request’s qname, this could lead to a crash References: #7810, pull request 7814
- Fix minor issues reported by Coverity References: pull request 7823
- Remove second, incomplete copy of lua EDNSOptionCode table References: pull request 7833

21.45 1.4.0-alpha2

Released: 26th of April 2019

Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.45.1 New Features

- Add DNS over HTTPS support based on libh2o References: #6911, #7526, pull request 7726

21.45.2 Improvements

- Ignore Path MTU discovery on UDP server socket References: pull request 7410
- Alternative solution to the unaligned accesses. References: pull request 7708

21.45.3 Bug Fixes

- Exit when setting ciphers fails (GnuTLS) References: pull request 7718

21.46 1.4.0-alpha1

Released: 12th of April 2019

Please review the Upgrade Guide before upgrading from versions < 1.4.x.

21.46.1 New Features

- Make recursor & dnsdist communicate (ECS) ‘variable’ status References: pull request 7209
- Add namespace and instance variable to carbon key (Gibheer) References: #2362, #6941, pull request 6959
- Allow NoRecurse for use in dynamic blocks or Lua rules (phonedph1) References: pull request 7087
- Expose secpoll status References: #7194, pull request 7197
- Add an optional ‘checkTimeout’ parameter to ‘newServer()’ References: #7236, pull request 7323
- Add a ‘rise’ parameter to ‘newServer()’ References: #7237, pull request 7322
- Add a ‘keepStaleData’ option to the packet cache References: #7239, pull request 7310
• Expose trailing data (Richard Gibson) References: #6846, #6897, pull request 6967
• Add option to set interval between health checks (1848) References: pull request 7142
• Add EDNS unknown version handling (Dmitry Alenichev) References: pull request 7406
• DNSNameSet and QNameSetRule (Andrey) References: pull request 7537
• Add support for encrypting ip addresses #gdpr References: #6242, pull request 7481
• Add ‘setSyslogFacility()’ References: #5653, pull request 7677
• Add ‘reloadAllCertificates()’ References: pull request 7676

21.46.2 Improvements

• Fix warnings, mostly unused parameters, reported by -wextra References: pull request 7168
• Add optional uuid column to showServers() References: pull request 7191
• Configure –enable-pdns-option –with-third-party-module (Josh Soref) References: pull request 7026
• Drop remaining capabilities after startup References: pull request 7138
• More sandboxing using systemd’s features References: pull request 6634
• Reduce syscall usage in Protobuf logging References: pull request 7428
• Resync YaHTTP code to cmouse/yahttp@11be77a1fc4032 (Chris Hofstaedtler) References: pull request 7433
• Pass empty response (Dmitry Alenichev) References: pull request 7431
• Change the way getRealMemusage() works on linux (using statm) References: pull request 7502
• Prevent 0-ttl cache hits References: #7534, pull request 7585
• Add addDynBlockSMT() support to dynBlockRulesGroup References: #7139, pull request 7343
• Add frontend response statistics (Matti Hiljanen) References: pull request 7578
• Remove addLuaAction and addLuaResponseAction References: pull request 7670
• Refactoring of the TCP stack References: #4814, #7526, pull request 7559
• Prevent a conflict with BADSIG being clobbered References: #7556, pull request 7692
• Switch to the new ‘newPacketCache()’ syntax for 1.4.0 References: pull request 7689
• Move constants to proper namespace References: pull request 7678
• Unify the management of DNS/DNSCrypt/DoT frontends References: pull request 7694
• Fix compiler warning about returning garbage (Adam Majer) References: pull request 7167

21.46.3 Bug Fixes

• Protect GnuTLS tickets key rotation with a read-write lock References: pull request 7256
• Check that SD_ATTACH_BPF is defined before enabling eBPF References: pull request 7267
• Fix off-by-one in mvRule counting References: pull request 7426
• Don’t convert nsec to usec if we need nsec References: pull request 7520
• Fix setRules() References: pull request 7594
• Handle EAGAIN in the GnuTLS DNS over TLS provider References: pull request 7560
• Gracefully handle a null latency in the webserver’s js References: #7461, pull request 7586

21.46. 1.4.0-alpha1
• EDNSOptionView improvements References: pull request 7652
• Honor libcrypto include path References: #7481, pull request 7674

21.47 1.3.3

Released: 8th of November 2018

Please review the Upgrade Guide before upgrading from versions < 1.3.x.

21.47.1 New Features

• Add consistent hash builtin policy References: #6932, pull request 6737, pull request 6939
• Add EDNSOptionRule References: pull request 6803
• Add DSTPortRule (phonedph1) References: pull request 6813
• Make getOutstanding usable from both lua and console (phonedph1) References: pull request 6826
• Added :excludeRange and :includeRange methods to DynBPFFilter class (Reinier Schoof) References: pull request 6856
• Add Prometheus stats support (Pavel Odintsov, Kai S) References: #4947, #6002, pull request 3935, pull request 6343, pull request 6901, pull request 7007, pull request 7089
• Name threads in the programs References: #6974, pull request 6997
• Support the NXDomain action with dynamic blocks References: #6908, pull request 7075
• Add security polling References: pull request 7115
• Add a PoolAvailableRule to easily add backup pools (Robin Geuze) References: pull request 7140

21.47.2 Improvements

• Get rid of some allocs/copies in DNS parsing References: pull request 6831
• Set a correct EDNS OPT RR for self-generated answers References: #4857, #6348, pull request 6847
• Fix a sign-comparison warning in isEDNSOptionInOPT() References: pull request 6877
• Add warning rates to DynBlockRulesGroup rules References: #6907, pull request 6986
• Add support for exporting a server id in protobuf References: #6990, #7004, pull request 7015
• dnsdist did not set TCP_NODELAY, causing needless latency References: pull request 7030
• Add a setting to control the number of stored sessions References: pull request 7062
• Wrap GnuTLS and OpenSSL pointers in smart pointers References: #7060, pull request 7064
• Add a ‘creationOrder’ field to rules References: #6909, pull request 7078
• Fix return-type detection with boost 1.69’s tribool References: #7091, pull request 7092
• Fix format string issue on 32bits ARM References: #7096, pull request 7104
• Wrap TCP connection objects in smart pointers References: pull request 7108
• Add the setConsoleOutputMaxMsgSize function References: #7084, pull request 7109
• Add the ability to update webserver credentials References: #7112, pull request 7117
21.47.3 Bug Fixes

- Display dynblocks’ default action, None, as the global one References: pull request 6835
- Fix compilation when SO_REUSEPORT is not defined References: pull request 6956
- Release memory on DNS over TLS handshake failure References: pull request 7060
- Handle trailing data correctly when adding OPT or ECS info References: #6896, pull request 7165

21.48 1.3.2

Released: 10th of July 2018
Please review the Upgrade Guide before upgrading from versions < 1.3.x.

21.48.1 Bug Fixes

- Add missing include for PRId64, fix build on CentOS 6 / SLES 12 References: pull request 6785

21.49 1.3.1

Released: 10th of July 2018
Please review the Upgrade Guide before upgrading from versions < 1.3.x.

21.49.1 New Features

- Add support for more than one TLS certificate References: #6450, pull request 6524
- Add a negative ttl option to the packet cache References: #6579, pull request 6740
- Add the ability to dump a summary of the cache content References: pull request 6749
- Add netmask-based {ex,in}clusions to DynblockRulesGroup References: pull request 6760
- Add DNSAction.NoOp to debug dynamic blocks References: #6703, pull request 6776
- Add SetECSAction to set an arbitrary outgoing ecs value References: #6404, pull request 6734
- Add support for rotating certificates and keys References: pull request 6764

21.49.2 Improvements

- Remove thelog and thel and replace this with a global g_log References: #6357, pull request 6358
- Fix two small nits on the documentation References: pull request 6422
- Move the el6 dnsdist package to upstart References: #6394, pull request 6426
- CLI option improvements (Chris Hofstaedtler) References: #6433, pull request 6435
- Split pdns_enable_unit_tests (Chris Hofstaedtler) References: pull request 6436
- Re-do lua detection References: #6423, pull request 6445, pull request 6457, pull request 6470
- Docs: fix missing ref in the dnsdist docs References: pull request 6460
- Be more permissive in wrandom tests, log values on failure References: pull request 6502
- Tests: avoid failure on not-so-optimal distribution References: #6430, pull request 6523
• Add syntax to dns.proto to silence compilation warning. References: pull request 6577
• Fix warnings reported by gcc 8.1.0 References: pull request 6590
• Document setVerboseHealthchecks() References: #6483, pull request 6592
• Update dq.rst (phonedph1) References: pull request 6615
• Fix rpm scriptlets References: pull request 6641
• Don’t copy uninitialized values of SuffixMatchTree References: pull request 6637
• Expose toString of various objects to Lua (Chris Hofstaedtler) References: pull request 6684
• Remove ‘expired’ states from MaxQPSIPRule References: pull request 6674
• Mark the remote member of DownstreamState as const References: #6664, pull request 6688
• Test the content of dynamic blocks using the API References: #6706, pull request 6710
• Default set “connection: close” header for web requests References: #6532, pull request 6711
• Update timedipsetrule.rst (phonedph1) References: pull request 6717
• Don’t access the TCP buffer vector past its size References: #6712, pull request 6716
• Show droprate in API output References: pull request 6563
• Refuse console connection without a proper key set References: #6683, #6709, pull request 6715
• Use LRU to clean the MaxQPSIPRule’s store References: pull request 6726
• Disable maybe uninitialized warnings with boost optional References: pull request 6769
• Luawrapper: report caught std::exception as lua_error References: #6541, pull request 6658
• Dnstap.rst: fix some editing errors (Chris Hofstaedtler) References: pull request 6602
• Allow known exception types to be converted to string References: #6535, pull request 6541

21.49.3 Bug Fixes

• Initialize the done variable in the rings’ unit tests References: pull request 6425
• Reorder headers to fix OpenBSD build References: pull request 6429
• Restrict value range for weight parameter, avoid sum overflows dropping queries (Dan McCombs) References: pull request 6448
• Fix reconnection handling References: pull request 6672
• Dynamic blocks were being created with the wrong duration (David Freedman) References: pull request 6706
• Limit qps and latency to two decimals in the web view References: #6442, pull request 6718
• Check the flags to detect collisions in the packet cache References: pull request 6747
• Fix iterating over the results of exceed*() functions References: pull request 6762
• Fix duration false positive in the dynblock regression tests References: pull request 6767
• Implement NoneAction() References: #6758, pull request 6775
• Detect ECS collisions in the packet cache References: #6747, pull request 6754
• Fix an outstanding counter race when reusing states References: pull request 6773
21.50 1.3.0

Released: 30th of March 2018

Please review the Upgrade Guide before upgrading from versions < 1.3.x.

21.50.1 New Features

- Add an optional status parameter to `Server:setAuto()`. References: pull request 5625
- Add `inClientStartup()` function. References: pull request 6072
- Add tag-based routing of queries. References: pull request 6037
- Add experimental DNS-over-TLS support. References: pull request 6117, pull request 6175, pull request 6176, pull request 6177, pull request 6189
- Add simple dnstap support (Justin Valentini, Chris Hofstaedtler). References: pull request 5201, pull request 6170
- Add experimental XPF support based on draft-bellis-dnsop-xpf-04. References: #5079, #5654, pull request 5594, pull request 6170
- Add `ERCodeRule()` to match on extended RCodes (Chris Hofstaedtler). References: pull request 6147
- Add `TempFailureCacheTTLAction()` (Chris Hofstaedtler). References: pull request 6003
- Add `DynBlockRulesGroup` to improve processing speed of the `maintenance()` function by reducing memory usage and not walking the ringbuffers multiple times. References: pull request 6391
- Add console ACL functions. References: #4654, pull request 6399
- Allow adding EDNS Client Subnet information to a query before looking in the cache. This allows serving ECS enabled answers from the cache when all servers in a pool are down. References: #6098, pull request 6400

21.50.2 Improvements

- Add cache sharding, `recvmmsg` and CPU pinning support. With these, the scalability of dnsdist is drastically improved. References: #5202, #5859, pull request 5576, pull request 5860
- Add burst option to `MaxQPSIPRule()` (42wim). References: pull request 5970
- Add Pools, cacheHitResponseRules to the API. References: pull request 6022
- Add a class option to health checks. References: #5748, pull request 5929
- Add UUIDs to rules, this allows tracking rules through modifications and moving them around. References: pull request 6030
- Apply ResponseRules to locally generated answers (Chris Hofstaedtler). References: #6182, pull request 6185
- Report `LuaAction()` and `LuaResponseAction()` failures in the log and send SERVFAIL instead of not answering the query (Chris Hofstaedtler). References: pull request 6283
- Unify global statistics accounting (Chris Hofstaedtler). References: pull request 6289
- Speed up the processing of large ring buffers. This change will make dnsdist more scalable with a large number of different clients. References: pull request 6350, pull request 6366
- Make custom `addLuaAction()` and `addLuaResponseAction()` callback’s second return value optional. References: #6346, pull request 6363
- Add “server-up” metric count to Carbon Reporting (Lowell Mower). References: pull request 6327
- Add xchacha20 support for DNSCrypt. References: pull request 6045, pull request 6382
• Scalability improvement: Add an option to use several source ports towards a backend. References: pull request 6317

• Add ‘?’ and ‘help’ for providing help() output on dnsdist -c (Kirill Ponomarev, Chris Hofstaedtler). References: #4845, pull request 5866, pull request 6375

• Replace the Lua mutex with a rw lock to limit contention. This improves the processing speed and parallelism of the policies. References: pull request 6190, pull request 6381

• Ensure dnsdist compiles on NetBSD (Tom Ivar Helbekkmo). References: pull request 6146

• Also log eBPF dynamic blocks, as regular dynamic block already are. References: #5845, pull request 5845

• Ensure large numbers are shown correctly in the API. References: #6211, pull request 6401

• Add option to showRules() to truncate the output length. References: #5763, pull request 6402

• Fix several warnings reported by clang’s analyzer and cppcheck, should lead to small performance increases. References: pull request 6407

### 21.50.3 Bug Fixes

• Handle SNMP alarms so we can reconnect to the daemon. References: #5327, pull request 5328

• Fix signed/unsigned comparison warnings on ARM. References: #5489, pull request 5597

• Keep trying if the first connection to the remote logger failed References: pull request 5770

• Fix escaping unusual DNS label octets in DNSName is off by one (Kees Monshouwer). References: pull request 6018

• Avoid assertion errors in NewServer() (Chris Hofstaedtler). References: pull request 6403

### 21.50.4 Removals

• Remove the --daemon option from dnsdist. References: #6329, pull request 6394

### 21.51 1.2.1

Released: 16th of February 2018

Please review the Upgrade Guide before upgrading from versions < 1.2.x.

#### 21.51.1 New Features

• Add configuration option to disable IP_BIND_ADDRESS_NO_PORT (Dan McCombs). References: pull request 5880

#### 21.51.2 Improvements

• Handle bracketed IPv6 addresses without ports (Chris Hofstaedtler). References: pull request 6057
21.51.3 Bug Fixes

- Make dnsdist dynamic truncate do right thing on TCP/IP. References: pull request 5647
- Add missing QPSAction References: pull request 5686
- Don’t create a Remote Logger in client mode. References: pull request 5847
- Use libsocket’s CFLAGS, we might need them to find the includes. References: pull request 5858
- Keep the TCP connection open on cache hit, generated answers. References: pull request 6012
- Add the missing <sys/time.h> include to mplexer.hh for struct timeval. References: pull request 6041
- Sort the servers based on their ‘order’ after it has been set. References: pull request 6043
- Quiet unused variable warning on macOS (Chris Hofstaedtler). References: pull request 6073
- Fix the outstanding counter when an exception is raised. References: #5652, pull request 6094
- Do not connect the snmpAgent from a dnsdist client. References: #6163, pull request 6164

21.52 1.2.0

Released: 21st of August 2017

Please review the Upgrade Guide before upgrading from versions < 1.2.x.

21.52.1 New Features

- Add an option to export CNAME records over protobuf. References: #4709, pull request 4776
- Add TCP management options from RFC 7766 section 10. References: pull request 4611
- Add an option to ‘mute’ UDP responses per bind. References: #4527, pull request 4536
- Save history to home-dir, only use CWD as a last resort. References: #4562, pull request 4779
- Add the setRingBuffersSize() directive to allows changing the ringbuffer size. References: pull request 4898
- Allow TTL alteration via Lua. References: #4707, pull request 4787
- Add RDRule() to match queries with the RD flag set. References: pull request 4837
- Add setWHashedPertubation() for consistent whashed results. References: pull request 4897
- Add tcpConnectTimeout to newServer(). References: pull request 4818
- Add cache hit response rules. References: #4708, pull request 4788, pull request 5036
- Add SNMP support. References: pull request 4989, pull request 5123, pull request 5204
- Allow passing DNSNames as DNSRules. References: pull request 5070
- Add support for setting the server selection policy on a per pool basis (Robin Geuze). References: pull request 5113
- Add a suffixMatch parameter to PacketCache:expungeByName() (Robin Geuze). References: pull request 5159
- Add an option so the packet cache entries don’t age. References: #5126, pull request 5136
- Add QNameRule(). References: pull request 5235
- Add an optional action to addDynBlocks(). References: pull request 5337
- Add an optional interface parameter to addLocal()/setLocal(). References: pull request 5344
• Make a `truncate` action available to DynBlock and Lua. References: pull request 5386

• Implement a runtime changeable rule that matches IP address for a certain time called `TimedIPSetRule()`. References: pull request 5336

• Add support for returning several IPs to spoof from Lua. References: pull request 5496

• Add Lua bindings to be able to rotate DNSCrypt keys, see `DNSCrypt`. References: #5420, #5507, pull request 5490, pull request 5508

• Add the capability to set arbitrary tags in protobuf messages. References: pull request 5396, pull request 5577

• Add `setConsoleConnectionsLogging()`. References: #5565, pull request 5581

### 21.52.2 Improvements

• Merge the client and server nonces to prevent replay attacks. References: pull request 4815

• Store the computed shared key and reuse it for the response for DNSCrypt messages. References: pull request 4813, pull request 4926

• Add `setTCPUseSinglePipe()` to use a single TCP waiting queue. References: pull request 4817

• Add `sendSizeAndMsgWithTimeout` to send size and data in a single call and use it for TCP Fast Open towards backends. References: #5494, pull request 4985, pull request 5501

• Tune systemd unit-file for medium-sized installations (Winfried Angele). References: pull request 4958

• Add the possibility to fill a `NetmaskGroup` (using `NetmaskGroup::addMask()`) from `exceeds*` results. References: pull request 5185

• Add labels count to StatNode, only set the name once. References: pull request 5353

• DNSName: Check that both first two bits are set in compressed labels. References: #4851, pull request 4852

• Handle unreachable servers at startup, reconnect stale sockets References: #4131, #4155, pull request 4285

• Gracefully handle invalid addresses in `newServer()`. References: #4471, pull request 4474

• Use `IP_BIND_ADDRESS_NO_PORT` when available. References: pull request 4786

• Add an optional `seconds` parameter to `statNodeRespRing()`. References: #4660, #4775, pull request 4780

• Report a more specific lua version and report luajit in `--version`. References: pull request 4910

• Prevent issues by unshadowing variables. References: pull request 5056

• Register DNSName::`chopOff` (@plzz). References: pull request 4920

• Make `includeDirectory()` work sorted (Robin Geuze). References: #5053, pull request 5150, pull request 5171

• Allow embedded NULs in strings received from Lua. References: pull request 5147

• Cleanup closed TCP downstream connections. References: pull request 5163

• Improve reporting of C++ exceptions that bubble up via Lua. References: pull request 5230

• Add better logging on queries that get dropped, timed out or received. References: pull request 5253

• Print useful messages when query and response actions are mixed. References: pull request 5342

• Add `DNSRule::toString()` and add virtual destructors to `DNSRule`, `DNSAction` and `DNSResponseAction` so the destructors of derived classes are run even when deleted via the base type. References: pull request 5497

• Don’t use square brackets for IPv6 in Carbon metrics. References: #5538, pull request 5579
21.52.3 Bug Fixes

- Unified –k and setKey() behaviour for client and server mode now. References: pull request 5199
- Refactor SuffixMatchNode using a SuffixMatchTree. References: #4761, pull request 4950
- Get rid of std::move() calls preventing copy elision. References: pull request 5359
- Send an HTTP 404 on unknown API paths. References: pull request 5089
- LuaWrapper: Use the correct index when storing a function. References: pull request 4775
- Send a latency of 0 over carbon, null over API for down servers. References: #4689, pull request 4785
- Fix negative port detection for IPv6 addresses on 32-bit. References: pull request 4911
- Fix crashed on SmartOS/Illumos (Roman Dayneko). References: #4579, pull request 4877
- Change truncateTC to defaulting to off, having it enabled by default causes an compatibility with RFC 6891 (Robin Geuze). References: #4857, pull request 4859
- Don’t cache answers without any TTL (like SERVFAIL). References: #4983, pull request 4987, pull request 5037
- Fix destination port reporting on “any” binds. References: pull request 5194
- Correctly truncate EDNS Client Subnetmasks. References: pull request 5320
- Fix RecordsTypeCountRule()’s handling of the # of records in a section. References: #5365, pull request 5369
- Change stats functions to always return lowercase names (Robin Geuze). References: #5287, pull request 5383
- Only use TCP Fast Open when supported and prevent compiler warnings. References: pull request 5449, pull request 5454
- Skip timeouts on the response latency graph. References: #5559, pull request 5563
- Copy the DNS header before encrypting it in place. References: #5566, pull request 5580

21.52.4 Removals

- Remove BlockFilter. References: #5513, pull request 5514
- Deprecate syntactic sugar functions. References: #5069, pull request 5526

21.52.5 misc

- Fix potential pointer wrap-around on 32 bits. References: pull request 5630
- Make the API available with an API key only. References: pull request 5631

21.53 1.1.0

Released December 29th 2016
Changes since 1.1.0-beta2:

21.53.1 Improvements

- #4783: Add -latomic on powerpc
- #4812: Handle header-only responses, handle Refused as Servfail in the cache
21.53.2 Bug fixes

• #4762: SuffixMatchNode: Fix an insertion issue for an existing node
• #4772: Fix dnsdist initscript config check

21.54 1.1.0-beta2

Released December 14th 2016
Changes since 1.1.0-beta1:

21.54.1 New features

• #4518: Fix dynblocks over TCP, allow refusing dyn blocked queries
• #4519: Allow altering the ECS behavior via rules and Lua
• #4535: Add DNSQuestion:getDO()
• #4536: getStatisticsCounters() to access counters from Lua
• #4557: Add includeDirectory(dir)
• #4568: Allow editing the ACL via the API
• #4702: Add setUDPTimeout(n)
• #4726: Add an option to return ServFail when no server is available
• #4748: Add setCacheCleaningPercentage()

21.54.2 Improvements

• #4533: Fix building with clang on OS X and FreeBSD
• #4537: Replace luawrapper’s std::forward/std::make_tuple combo with std::forward_as_tuple (Sangwhan “fish” Moon)
• #4596: Change the default max number of queued TCP conns to 1000
• #4632: Improve dnsdist error message on a common typo/config mistake
• #4694: Don’t use a const_iterator for erasing (fix compilation with some versions of gcc)
• #4715: Specify that dnsmessage.proto uses protobuf version 2
• #4765: Some service improvements

21.54.3 Bug fixes

• #4425: Fix a protobuf regression (requestor/responder mix-up) caused by a94673e
• #4541: Fix insertion issues in SuffixMatchTree, move it to dnsname.hh
• #4553: Flush output in single command client mode
• #4578: Fix destination address reporting
• #4640: Don’t exit dnsdist on an exception in maintenance
• #4721: Handle exceptions in the UDP responder thread
• #4734: Add the TCP socket to the map only if the connection succeeds. Closes #4733
• #4742: Decrement the queued TCP conn count if writing to the pipe fails
• #4743: Ignore newBPFFilter() and newDynBPFFilter() in client mode
• #4753: Fix FD leak on TCP connection failure, handle TCP worker creation failure
• #4764: Prevent race while creating new TCP worker threads

21.55 1.1.0-beta1

Released September 1st 2016
Changes since 1.0.0:

21.55.1 New features

• #3762 Teeaction: send copy of query to second nameserver, sponge responses
• #3876 Add showResponseRules(), (mv, rm, top)ResponseRule()
• #3936 Filter on opcode, records count/type, trailing data
• #3975 Make dnsdist [A, I]XFR aware, document possible issues
• #4006 Add eBPF source address and qname/qtype filtering
• #4008 Node infrastructure for querying recent traffic
• #4042 Add server-side TCP Fast Open support
• #4050 Add clearRules() and setRules()
• #4114 Add QNameLabelsCountRule() and QNameWireLengthRule()
• #4116 Added src boolean to NetmaskGroupRule to match destination address (Reinier Schoof)
• #4175 Implemented query counting (Reinier Schoof)
• #4244 Add a setCD parameter to set cd=1 on health check queries
• #4284 Add RCodeRule(), Allow, Delay and Drop response actions
• #4305 Add an optional Lua callback for altering a Protobuf message
• #4309 Add showTCPStats function (RobinGeuze)
• #4329 Add options to LogAction() so it can append (instead of truncate) (Duane Wessels)

21.55.2 Improvements

• #3714 Add documentation links to dnsdist.service (Ruben Kerkhof)
• #3754 Allow the use of custom headers in the web server
• #3826 Implement a ‘quiet’ mode for SuffixMatchNodeRule()
• #3836 Log the content of webserver’s exceptions
• #3858 Only log YaHTTP’s parser exceptions in verbose mode
• #3877 Increase max FDs in systemd unit, warn if clearly too low
• #4019 Add an optional addECS option to TeeAction()
• #4029 Add version and feature information to version output
• #4079 Return an error on RemoteLog{,Response}Action() w/o protobuf
• #4246 API now sends pools as a JSON array instead of a string
21.55.3 Bug fixes

- #3755 Fix RegexRule example in dnsdistconf.lua
- #3773 Stop copying the HTTP request headers to the response
- #3837 Remove dnsdist service file on trusty
- #3840 Catch WrongTypeException in client mode
- #3906 Keep the servers ordered inside pools
- #3988 Fix grepq() output in the README
- #3992 Fix some typos in the AXFR/IXFR documentation
- #3995 Fix comparison between signed and unsigned integer
- #4049 Fix dnsdist rpm building script #4048 (Daniel Stirnimann)
- #4065 Include editline/readline.h instead of readline.h/history.h
- #4067 Disable eBPF support when BPF_FUNC_tail_call is not found
- #4069 Fix a buffer overflow when displaying an OpcodeRule
- #4101 Fix $ expansion in build-dnsdist-rpm
- #4198 newServer setting maxCheckFailures makes no sense (stutiredboy)
- #4205 Prevent the use of “any” addresses for downstream server
- #4220 Don’t log an error when parsing an invalid UDP query
- #4348 Fix invalid outstanding count for {A,I}XFR over TCP
- #4365 Reset origFD asap to keep the outstanding count correct
- #4375 Tuple requires make_tuple to initialize
- #4380 Fix compilation with clang when eBPF support is enabled

21.56 1.0.0

Released April 21st 2016
Changes since 1.0.0-beta1:

21.56.1 Improvements

- #3700 Create user from the RPM package to drop privs
- #3712 Make check should run testrunner
- #3713 Remove contrib/dnsdist.service (Ruben Kerkhof)
- #3722 Use LT_INIT and disable static objects (Ruben Kerkhof)
- #3724 Include PDNS_CHECK_OS in configure (Chris Hofstaedtler)
- #3728 Document libedit Ctrl-R workaround for CentOS 6
- #3730 Make topBandwidth() behave like other top* functions
• #3731 Clarify a bit the documentation of load-balancing policies

21.56.2 Bug fixes

• #3711 Building rpm needs systemd headers (Ruben Kerkhof)
• #3736 Add missing Lua binding for NetmaskGroupRule()
• #3739 Drop privileges after daemonizing and writing our pid

21.57 1.0.0-beta1

Released April 14th 2016
Changes since 1.0.0-alpha2:

21.57.1 New features

• Per-pool packet cache
• Some actions do not stop the processing anymore when they match, allowing more complex setups: Delay, Disable Validation, Log, MacAddr, No Recurse and of course None
• The new RE2Rule() is available, using the RE2 regular expression library to match queries, in addition to the existing POSIX-based RegexRule()
• SpoofAction() now supports multiple A and AAAA records
• Remote logging of questions and answers via Protocol Buffer

21.57.2 Improvements

• #3405 Add health check logging, maxCheckFailures to backend
• #3412 Check config
• #3440 Client operation improvements
• #3466 Add dq binding for skipping packet cache in LuaAction (Jan Broer)
• #3499 Add support for multiple carbon servers
• #3504 Allow accessing the API with an optional API key
• #3556 Add an option to limit the number of queued TCP connections
• #3578 Add a disable-syslog option
• #3608 Export cache stats to carbon
• #3622 Display the ACL content on startup
• #3627 Remove ECS option from response’s OPT RR when necessary
• #3633 Count “TTL too short” cache events
• #3677 systemd-notify support
21.57.3 Bug fixes

- #3388 Lock the Lua context before executing a LuaAction
- #3433 Check that the answer matches the initial query
- #3461 Fix crash when calling rmServer() with an invalid index
- #3550,#3551 Fix build failure on FreeBSD (Ruben Kerkhof)
- #3594 Prevent EOF error for empty console response w/o sodium
- #3634 Prevent dangling TCP fd in case setupTCPDownstream() fails
- #3641 Under threshold, QPS action should return None, not Allow
- #3658 Fix a race condition in MaxQPSIPRule

21.58 1.0.0-alpha2

Released February 5th 2016
Changes since 1.0.0-alpha1:

21.58.1 New features

- Lua functions now receive a DNSQuestion dq object instead of several parameters. This adds a greater compatibility with PowerDNS and allows adding more parameters without breaking the API (#3198)
- Added a source option to newServer() to specify the local address or interface used to contact a downstream server (#3138)
- CNAME and IPv6-only support have been added to spoofed responses (#3064)
- grepq() can be used to search for slow queries, along with topSlow()
- New Lua functions: addDomainCNAMESpoof(), AllowAction() by @bearggg, exceedQRate(),MacAddrAction(),makeRule(),NotRule(),OrRule(),QClassRule(), RCodeAction(), SpoofCNAMEAction(), SuffixMatchNodeRule(), TCPRule(), topSlow()
- NetmaskGroup support have been added in Lua (#3144)
- Added MacAddrAction() to add the source MAC address to the forwarded query (#3313)

21.58.2 Bug fixes

- An issue in DelayPipe could make dnsdist crash at startup
- downstream-timeouts metric was not always updated
- truncateTC was improperly updating the response length (#3126)
- DNSCrypt responses larger than queries were improperly truncated
- An issue prevented info message from being displayed in non-verbose mode, fixed by Jan Broer
- Reinstating an expired Dynamic Rule was not correctly logged (#3323)
- Initialized counters in the TCP client thread might have cause FD and memory leak, reported by Martin Pels (#3300)
- We now drop queries containing no question (qdcount == 0) (#3290)
- Outstanding TCP queries count was not always correct (#3288)
• A locking issue in exceedRespGen() might have caused crashes (#3277)
• Useless sockets were created in client mode (#3257)
• addAnyTCRule() was generating TC=1 responses even over TCP (#3251)

21.58.3 Web interface

• Cleanup of the HTML by Sander Hoentjen
• Fixed an XSS reported by @janeczku (#3217)
• Removed remote images
• Set the charset to UTF-8, added some security-related and CORS HTTP headers
• Added server latency by Jan Broer (#3201)
• Switched to official minified versions of JS scripts, by Sander Hoentjen (#3317)
• Don’t log unauthenticated HTTP request as an authentication failure

21.58.4 Various documentation updates and minor cleanups:

• Added documentation for Advanced DNS Protection features (Dynamic rules, maintenance())
• Make topBandwidth() default to the top 10 clients
• Replaced readline with libedit
• Added GPL2 License (#3200)
• Added incbin License (#3269)
• Updated completion rules
• Removed wrong option --daemon-no by Stefan Schmidt

21.59 1.0.0-alpha1

Released December 24th 2015
Initial release
22.1 1.8.x to 1.9.0

dnsdist now supports a new library for dealing with incoming DNS over HTTPS queries: nghttp2. The previously used library, h2o, can still be used but is now deprecated, disabled by default (see --with-h2o to enable it back) and will be removed in the future, as it is unfortunately no longer maintained in a way that is suitable for use as a library (see https://github.com/h2o/h2o/issues/3230). See the library parameter on the addDOHLocal() directive for more information on how to select the library used when dnsdist is built with support for both h2o and nghttp2. The default is now nghttp2 whenever possible. Note that nghttp2 only supports HTTP/2, and not HTTP/1, while h2o supported both. This is not an issue for actual DNS over HTTPS clients that support HTTP/2, but might be one in setups running dnsdist behind a reverse-proxy that does not support HTTP/1. See DNS-over-HTTPS (DoH) for some work-around.

SNMP support is no longer enabled by default during configure, requiring --with-net-snmp to be built.

The use of makeRule() is now deprecated, please use NetmaskGroupRule() or QNameSuffixRule() instead. Passing a string or list of strings instead of a DNSRule to these functions is deprecated as well; NetmaskGroupRule() and QNameSuffixRule() should there again be used instead:

• addAction()
• addResponseAction()
• addCacheHitResponseAction()
• addCacheInsertedResponseAction()
• addSelfAnsweredResponseAction()

22.2 1.7.x to 1.8.0

Responses to AXFR and IXFR queries are no longer cached.

Cache-hits are now counted as responses in our metrics.

The setMaxTCPConnectionsPerClient() limit is now properly applied to DNS over HTTPS connections, in addition to DNS over TCP and DNS over TLS ones.

The configuration check will now fail if the configuration file does not exist. For this reason we now create a default configuration file, based on the file previously called dnsdistconf.lua, which contains commented-out examples of how to set up dnsdist.

Latency metrics have been broken down:

• per incoming protocol (Do53 UDP, Do53 TCP, DoT, DoH) for global latency metrics
• between UDP (Do53) and TCP (Do53 TCP, DoT, DoH) for backend latency metrics
22.3 1.7.0 to 1.7.1

In our Docker image, our binaries are no longer granted the `net_bind_service` capability, as this is unnecessary in many deployments. For more information, see the section “Privileged ports” in Docker-README. (This note was in the 1.6.x to 1.7.0 upgrade guide before, but the change was not present in 1.7.0.)

22.4 1.6.x to 1.7.0

Truncated responses received over UDP for DoH clients will now be retried over TCP.

`setTCPUseSinglePipe()` has been removed.

Unless set via `setMaxTCPClientThreads()` the number of TCP workers now defaults to 10, instead of the number of TCP binds.

Plain-text API keys and passwords for web server authentication are now strongly discouraged. The `hashPassword()` method can be used to generate a hashed and salted version of passwords and API keys instead, so that the plain-text version can no longer be found in either the configuration file or the memory of the running process.

22.5 1.5.x to 1.6.0

The packet cache no longer hashes EDNS Cookies by default, which means that two queries that are identical except for the content of their cookie will now be served the same answer. This only works if the backend is not returning any answer containing EDNS Cookies, otherwise the wrong cookie might be returned to a client. To prevent this, the `cookieHashing=true` parameter might be passed to `newPacketCache()` so that cookies are hashed, resulting in separate entries in the packet cache.

All TCP worker threads are now created at startup, instead of being created on-demand. The existing behaviour was useful for very small setups but did not scale quickly to a large amount of TCP connections. The new behaviour can cause a noticeable increase of TCP connections between dnsdist and its backends, as the TCP connections are not shared between TCP worker threads. This is especially true for setups with a large number of frontends (`addLocal()`, `addTLSSLocal()`, and `addDNSCryptBind()` directives), as 1.6.0 sets the number of TCP workers to the number of TCP-enabled binds (with a minimum of 10), unless that number has been set explicitly via `setMaxTCPClientThreads()`.

Several actions have been renamed so that almost all actions that allow further processing of rules start with ‘Set’, to prevent mistakes:

- `DisableECSAction` to `SetDisableECSAction()`
- `DisableValidationAction` to `SetDisableValidationAction()`
- `ECSOverrideAction` to `SetECSOverrideAction()`
- `ECSPrefixLengthAction` to `SetECSPrefixLengthAction()`
- `MacAddrAction` to `SetMacAddrAction()`
- `NoRecurseAction` to `SetNoRecurseAction()`
- `SkipCacheAction` to `SetSkipCacheAction()`
- `TagAction` to `SetTagAction()`
- `TagResponseAction` to `SetTagResponseAction()`
- `TempFailureCacheTTLACTION` to `SetAdditionalProxyProtocolValueAction()`
- `SetNegativeAndSOAAction` to `NegativeAndSOAAction()`

Some ambiguous commands have also been renamed to prevent mistakes:
• `topCacheHitResponseRule` to `mvCacheHitResponseRuleToTop()`
• `topResponseRule` to `mvResponseRuleToTop()`
• `topRule` to `mvRuleToTop()`
• `topSelfAnsweredResponseRule` to `mvSelfAnsweredResponseRuleToTop()`

The use of additional parameters on the `webserver()` command has been deprecated in favor of using `setWebserverConfig()`.

Regular users should not be impacted by this change, but packagers should be aware that since 1.6.0 dnssdist now uses the C++17 standard instead of the C++11 one it was previously using.

### 22.6 1.4.x to 1.5.0

DOH endpoints specified in the fourth parameter of `addDOHLocal()` are now specified as exact paths instead of path prefixes. The default endpoint also switched from `/` to `/dns-query`. For example, `addDOHLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', { "/dns-query" })` will now only accept queries for `/dns-query` and no longer for `/dns-query/foo/bar`. This change also impacts the HTTP response rules set via `DOHFrontend:setResponsesMap()`, since queries whose paths are not allowed will be discarded before the rules are evaluated. If you want to accept DoH queries on `/dns-query` and redirect `/rfc` to the DoH RFC, you need to list `/rfc` in the list of paths:

```lua
addDOHLocal('2001:db8:1:f00::1', '/etc/ssl/certs/example.com.pem', '/etc/ssl/private/example.com.key', { '/dns-query', '/rfc' })
map = { newDOHResponseMapEntry('^/rfc$', 307, "https://www.rfc-editor.org/info/rfc8484") }
dohFE = getDOHFrontend(0)
dohFE:setResponsesMap(map)
```

The systemd service-file that is installed no longer uses the `root` user to start. It uses the user and group set with the `--with-service-user` and `--with-service-group` switches during configuration, “dnssdist” by default. This could mean that dnssdist can no longer read its own configuration, or other data. It is therefore recommended to recursively `chown` directories used by dnssdist:

```
chown -R root:dnssdist /etc/dnsdist
```

Packages provided on the PowerDNS Repository will `chown` directories created by them accordingly in the post-installation steps.

This might not be sufficient if the dnssdist configuration refers to files outside of the `/etc/dnsdist` directory, like DoT or DoH certificates and private keys. Many ACME clients used to get and renew certificates, like CertBot, set permissions assuming that services are started as root. For that particular case, making a copy of the necessary files in the `/etc/dnsdist` directory is advised, using for example CertBot’s `--deploy-hook` feature to copy the files with the right permissions after a renewal.

The `webserver()` configuration now has an optional ACL parameter, that defaults to “127.0.0.1, ::1”.

### 22.7 1.3.x to 1.4.0

`addLuaAction()` and `addLuaResponseAction()` have been removed. Instead, use `addAction()` with a `LuaAction()`, or `addResponseAction()` with a `LuaResponseAction()`.

`newPacketCache()` now takes an optional table as its second argument, instead of several optional parameters.

Lua’s constants for DNS response codes and QTypes have been moved from the ‘dnssdist’ prefix to, respectively, the ‘DNSQType’ and ‘DNSRCode’ prefix.
To improve security, all ambient capabilities are now dropped after the startup phase, which might prevent launching the webserver on a privileged port at run-time, or impact some custom Lua code. In addition, systemd’s sandboxing features are now determined at compile-time, resulting in more restrictions on recent distributions. See pull requests 7138 and 6634 for more information.

If you are compiling dnsdist, note that several ./configure options have been renamed to provide a more consistent experience. Features that depend on an external component have been prefixed with ‘--with-’ while internal features use ‘--enable-’. This lead to the following changes:

- `--enable-fstrm` to `--enable-dnstap`
- `--enable-gnutls` to `--with-gnutls`
- `--enable-libsodium` to `--with-libsodium`
- `--enable-libssl` to `--with-libssl`
- `--enable-re2` to `--with-re2`

### 22.8 1.3.2 to 1.3.3

When upgrading from a package before 1.3.3, on CentOS 6 and RHEL 6, dnsdist will be stopped instead of restarted.

### 22.9 1.2.x to 1.3.x

In version 1.3.0, these things have changed.

The Working with the dnsdist Console has an ACL now, which is set to 
```
{"127.0.0.0/8", "::1/128"}
```
by default. Add the appropriate `setConsoleACL()` and `addConsoleACL()` statements to the configuration file.

The `--daemon` option is removed from the dnsdist binary, meaning that dnsdist will not fork to the background anymore. Hence, it can only be run on the foreground or under a supervisor like systemd, supervisord and daemon.

Due to changes in the architecture of dnsdist, several of the shortcut rules have been removed after deprecating them in 1.2.0. All removed functions have their equivalent `addAction()` listed. Please check the configuration for these statements (or use dnsdist --check-config) and update where needed. This removal affects the following functions:

- `addAnyTCRule()`
- `addDelay()`
- `addDisableValidationRule()`
- `addDomainBlock()`
- `addDomainCNAMEspoof()`
- `addDomainSpoof()`
- `addNoRecurseRule()`
- `addPoolRule()`
- `addQPSLimit()`
- `addQPSPoolRule()`
22.10 1.1.0 to 1.2.0

In 1.2.0, several configuration options have been changed:

As the amount of possible settings for listen sockets is growing, all listen-related options must now be passed as a table as the second argument to both `addLocal()` and `setLocal()`. See the function’s reference for more information.

The `BlockFilter` function is removed, as `addAction()` combined with a `DropAction()` can do the same.
All security advisories for the DNSDist are listed here.

23.1 PowerDNS Security Advisory 2017-01 for dnsdist: Crafted backend responses can cause a denial of service

- CVE: CVE-2016-7069
- Date: 2017-08-21
- Credit: Guido Vranken
- Affects: dnsdist up to and including 1.2.0 on 32-bit systems
- Not affected: dnsdist 1.2.0, dnsdist on 64-bit (all versions)
- Severity: Low
- Impact: Degraded service or Denial of service
- Exploit: This issue can be triggered by sending specially crafted response packets from a backend
- Risk of system compromise: No
- Solution: Upgrade to a non-affected version
- Workaround: Disable EDNS Client Subnet addition

An issue has been found in dnsdist in the way EDNS0 OPT records are handled when parsing responses from a backend. When dnsdist is configured to add EDNS Client Subnet to a query, the response may contain an EDNS0 OPT record that has to be removed before forwarding the response to the initial client. On a 32-bit system, the pointer arithmetic used when parsing the received response to remove that record might trigger an undefined behavior leading to a crash.

dnsdist up to and including 1.1.0 is affected on 32-bit systems. dnsdist 1.2.0 is not affected, dnsdist on 64-bit systems is not affected.

For those unable to upgrade to a new version, a minimal patch is available for 1.1.0

We would like to thank Guido Vranken for finding and subsequently reporting this issue.

23.2 PowerDNS Security Advisory 2017-02 for dnsdist: Alteration of ACLs via API authentication bypass

- CVE: CVE-2017-7557
- Date: 2017-08-21
- Credit: Nixu
An issue has been found in dnsdist 1.1.0, in the API authentication mechanism. API methods should only be available to a user authenticated via an X-API-Key HTTP header, and not to a user authenticated on the webserver via Basic Authentication, but it was discovered by Nixu during a source code audit that dnsdist 1.1.0 allows access to all API methods to both kinds of users.

In the default configuration, the API does not provide access to more information than the webserver does, and therefore this issue has no security implication. However if the API is allowed to make configuration changes, via the setAPIWritable(true) option, this allows a remote unauthenticated user to trick an authenticated user into editing dnsdist’s ACLs by making him visit a crafted website containing a Cross-Site Request Forgery.

For those unable to upgrade to a new version, a minimal patch is available for 1.1.0.

### 23.3 PowerDNS Security Advisory for dnsdist 2018-08: Record smuggling when adding ECS or XPF

- CVE: CVE-2018-14663
- Date: November 8th 2018
- Affects: PowerDNS DNSDist up to and including 1.3.2
- Not affected: 1.3.3
- Severity: Low
- Impact: Insufficient validation
- Exploit: This problem can be triggered via crafted queries
- Risk of system compromise: No
- Solution: Upgrade to a non-affected version

An issue has been found in PowerDNS DNSDist allowing a remote attacker to craft a DNS query with trailing data such that the addition of a record by dnsdist, for example an OPT record when adding EDNS Client Subnet, might result in the trailing data being smuggled to the backend as a valid record while not seen by dnsdist. This is an issue when dnsdist is deployed as a DNS Firewall and used to filter some records that should not be received by the backend. This issue occurs only when either the `useClientSubnet` or the experimental `addXPF` parameters are used when declaring a new backend.

This issue has been assigned CVE-2018-14663 by Red Hat.

PowerDNS DNSDist up to and including 1.3.2 is affected.

We would like to thank Richard Gibson for finding and subsequently reporting this issue.

If you have a security problem to report, please see our security policy.
POWERDNS SECURITY POLICY

If you have a security problem to report, please email us at both peter.van.dijk@powerdns.com and remi.gacogne@powerdns.com. In case you want to encrypt your report using PGP, please use: https://doc.powerdns.com/powerdns-keyblock.asc

Please do not mail security issues to public lists, nor file a ticket, unless we do not get back to you in a timely manner. We fully credit reporters of security issues, and respond quickly, but please allow us a reasonable timeframe to coordinate a response.

We remind PowerDNS and dnsdist users that under the terms of the GNU General Public License, PowerDNS and dnsdist come with ABSOLUTELY NO WARRANTY. This license is included in this documentation.

If you believe you have found a security vulnerability that applies to DNS implementations generally, and you want to report this responsibly to a number of implementers, you might consider also using the Open Source DNS Vulnerability mailing list, managed by DNS-OARC.

24.1 YesWeHack

Security issues can also be reported on our YesWeHack page and might fetch a bounty. Do note that only the PowerDNS software is in scope for the YesWeHack program, not our websites or other infrastructure.

24.2 Disclosure Policy

- Let us know as soon as possible upon discovery of a potential security issue, and we’ll make every effort to quickly resolve the issue.
- Provide us a reasonable amount of time to resolve the issue before any disclosure to the public or a third-party.
- We will always credit researchers in our Security Advisories.
GLOSSARY

ACL  Access Control List

Open Resolver  A recursive DNS server available for many hosts on the internet. Usually without adequate rate-limiting, allowing it to be used in reflection attacks.

QPS  Queries Per Second
We remind PowerDNS and dnsdist users that under the terms of the GNU General Public License, PowerDNS and
dnsdist come with ABSOLUTELY NO WARRANTY.

---

**GNU GENERAL PUBLIC LICENSE**
Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.,
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

Preamble

The licenses for most software are designed to take away your
freedom to share and change it. By contrast, the GNU General Public
License is intended to guarantee your freedom to share and change free
software--to make sure the software is free for all its users. This
General Public License applies to most of the Free Software
Foundation's software and to any other program whose authors commit to
using it. (Some other Free Software Foundation software is covered by
the GNU Lesser General Public License instead.) You can apply it to
your programs, too.

When we speak of free software, we are referring to freedom, not
price. Our General Public Licenses are designed to make sure that you
have the freedom to distribute copies of free software (and charge for
this service if you wish), that you receive source code or can get it
if you want it, that you can change the software or use pieces of it
in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid
anyone to deny you these rights or to ask you to surrender the rights.
These restrictions translate to certain responsibilities for you if you
distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether
ggratis or for a fee, you must give the recipients all the rights that
you have. You must make sure that they, too, receive or can get the
source code. And you must show them these terms so they know their
rights.

We protect your rights with two steps: (1) copyright the software, and
(2) offer you this license which gives you legal permission to copy,
distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain
that everyone understands that there is no warranty for this free
software. If the software is modified by someone else and passed on, we

(continues on next page)
want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

GNU GENERAL PUBLIC LICENSE
TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

0. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The "Program", below, refers to any such program or work, and a "work based on the Program" means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or translated into another language. (Hereinafter, translation is included without limitation in the term "modification".) Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

1. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

2. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:

   a) You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.

   b) You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.

   c) If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a
notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

3. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:

   a) Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

   b) Accompany it with a written offer, valid for at least three years, to give any third party, for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

   c) Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent
access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

4. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.

5. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.

6. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.

7. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.
8. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.

9. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and "any later version", you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

10. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

NO WARRANTY

11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

END OF TERMS AND CONDITIONS

How to Apply These Terms to Your New Programs

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each source file to most effectively
convey the exclusion of warranty; and each file should have at least the "copyright" line and a pointer to where the full notice is found.

<one line to give the program's name and a brief idea of what it does.>
Copyright (C) <year> <name of author>

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

Gnomovision version 69, Copyright (C) year name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type "show w". This is free software, and you are welcome to redistribute it under certain conditions; type "show c" for details.

The hypothetical commands "show w" and "show c" should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than "show w" and "show c"; they could even be mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a "copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

Yoyodyne, Inc., hereby disclaims all copyright interest in the program "Gnomovision" (which makes passes at compilers) written by James Hacker.

<signature of Ty Coon>, 1 April 1989
Ty Coon, President of Vice

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Lesser General Public License instead of this License.
